Dr. Janes, would you care to comment on Royal Air Force fusions of the ankle? You have had more experience with them than anybody.

Dr. Janes:

I don't know too much about them. In the Royal Air Force we did use tibial bone instead of the fibula at times, because the tibial graft is better shaped than the fibula and also because not much of the fibula is left after it has been shaped. In short, a piece of tibia can be used instead of the fibula.

Dr. Richard S. Bryan:*

One can use the same approach as in this procedure when one employs a compression plate to promote fusion of the arthrodesis and uses the fibula as a graft in the same way.

Dr. Bickel:

Dr. Janes, it is my understanding that this type of arthrodesis was first used in the Royal Air Force for comminuted fractures of the talus without involvement of the subtalar joint. Is that right?

Dr. Janes:

That is true, but a tibiocalcaneal arthrodesis can also be done by this method.

Dr. Bickel:

Yes. A Royal Air Force fusion really applies to an ankle joint only, or is it an ankle joint plus a subtalar joint arthrodesis?

Dr. Janes:

Most of them are done for fracture of the talus involving the ankle joint.

Dr. Lowell F. A. Peterson:†

The Chuinard operation is done with the iliac graft. Chuinard performs compression arthrodesis by impacting an iliac graft into a mortice cut vertically across the anterior portion of the ankle joint.

Dr. Coventry:

Is the approach an anterior one?

Dr. L. Peterson:

Yes. The graft is driven firmly between the talus and the tibia. This operation does not require any remodeling of the articular surface of the talus.

Dr. Bickel:

He developed this arthrodesis, did he not, Dr. Peterson, for the child who needs an arthrodesed ankle but in whom he could hope to preserve the distal tibial epiphysis?

Dr. L. Peterson:

Yes. It has worked well in my hands. As I recall, in the series that Chuinard and colleagues reported they included a number of adults as well, and there were no instances of nonunion. It is a nice way of using a limited approach and not changing the contour of the ankle at all.

Dr. Bickel:

A prerequisite is that the ankle must not be deformed, because one cannot

---

*Consultant, Section of Orthopedic Surgery, Mayo Clinic, Rochester.

†Assistant Professor of Orthopedic Surgery, Mayo Graduate School of Medicine (University of Minnesota), Rochester, and Consultant, Section of Orthopedic Surgery, Mayo Clinic, Rochester.

correct a deformity by doing an arthrodesis in the Chuinard fashion.

Dr. L. Peterson:

Yes, this is true; the procedure does not permit much correction of a deformity in a child.

Dr. Bickel:

In essence, one distracts the articular surface of the ankle, puts a wedge, or cookie, or block of iliac bone between the articular surfaces that have been freshened, and allows the soft tissues to contract and thus supply dynamic or physiologic compression. In other words, it's a type of compression arthrodesis which attempts, in a child, not to destroy the tibial epiphysis.

Dr. Coventry:

I think we have all used this idea specifically.

Dr. Patrick J. Kelly:*

We talk about compression in an arthrodesis of the ankle, but this is not really what we mean. We are trying to get the raw bone surfaces pulled together. The Charnley compression apparatus for the ankle works so well because it closely approximates the raw joint surfaces. A problem that I wonder about with a Royal Air Force fusion is one that I have seen. The surgeon tends to take off too much laterally and ends up with the talus tilted into a valgus position.

Dr. Coventry:

The same occurs with triple arthrodesis or anything else in a lateral approach. The surgeon is likely to remove more bone where he is working and less at the end of the osteotome. Is that what you mean, Dr. Kelly?

Dr. Kelly:

Well, one could get a little idea of it on the anteroposterior x-ray view.

Dr. Coventry:

The same with triple arthrodesis?

Dr. Kelly:

Yes, one could do a triple arthrodesis and end up with a valgus foot.

Dr. Einer W. Johnson, Jr.:†

This has been my problem and one of the reasons that I have had to forego doing Royal Air Force arthrodesis of the ankle—not because there is anything wrong with the procedure, but because I could not, as Dr. Coventry says, be fully confident that, at the end of the osteotome, I was not taking a piece of the posterior tibial nerve or the area of the posterior tibial tendon or something else. I like an anterior approach and, as Dr. Bianco brought up once when we talked this over, one cannot use compression across an ankle joint unless one osteotomizes both malleoli. It is rather hard for me to osteotomize the medial malleolus and remove enough of it so that it is not a factor in distraction, that is, not in the way of compression. It is hard for me to get to the medial malleolus from the lateral side. I like to do an ankle

*Associate Professor of Orthopedic Surgery, Mayo Graduate School of Medicine (University of Minnesota), Rochester, and Consultant, Section of Orthopedic Surgery, Mayo Clinic, Rochester.

†Associate Professor of Surgery, Mayo Graduate School of Medicine (University of Minnesota), Rochester, and Consultant, Section of Orthopedic Surgery, Mayo Clinic, Rochester.

arthrodesis from the directly anterior approach so that I can see everything, including both malleoli, and can dissect around posteriorly and do everything I want to do within convenient reach. I am not criticizing the Royal Air Force procedure; I am just saying I cannot do it.

Dr. Bickel:

In defense of the Royal Air Force type of arthrodesis I would say that I not infrequently have made a medial incision and removed the malleolus so that I am not too far away from my work. Then I am able to get good medial displacement of the talus, obtain satisfactory approximation of the raw surfaces, and avoid any valgus position. Approximation, retention, and some compression can then be obtained with the use of large vitallium staples. I like the procedure.

Dr. L. Peterson:

My opinion is that leg length is somewhat of a problem and one does not want to shorten it any further. This is again an advantage of the Chuinard procedure, because it does not alter length at all.

Dr. Lipscomb:

Along that same line, a Galley subtalar arthrodesis works if there is little motion in the ankle joint. I think all these methods have their place, and one should pick the method for the condition that is present when the arthrodesis is done. Obviously, if the foot is severely deformed, it should be corrected before arthrodesis is performed.

Dr. Johnson:

How did this one turn out? Did he get along well after the ankle arthrodesis? Could he walk on a side hill without distress?

Dr. Detenbeck:

He did well. He had minimal distress walking on a side hill, and he could get around on flat surfaces without trouble.

Dr. Bickel:

In conclusion, these two complicated fractures involving the ankle joint demonstrate some important aspects of treatment. First, although swelling may be massive and may dictate use of a padded dressing after closed reduction, this type of a dressing is usually not able to maintain the reduction. A far better method is to apply a cast that is well molded and then is split to allow for swelling. Second, open reduction and internal fixation of the medial malleolus are needed to stabilize the other two malleoli in the event of a trimalleolar fracture. If comminution is not marked, this is a rewarding and usually easy surgical exercise. Third, no matter how adequate the reduction, severe injuries about the ankle joint often lead to degenerative joint changes that require arthrodesis.

Trauma Conference

Gas Gangrene in a Diabetic

GAS GANGRENE in the foot secondary to trauma is a devastating infection and occurs not uncommonly in diabetics. Two factors seem to predispose the diabetic to this particularly virulent infection: (1) a neuropathy that allows an injury or sore callus to go unheeded and (2) a peripheral type of endarterial vascular disease that devascularizes the distal tissue and thereby provides an excellent culture media for growth of anaerobic bacteria.

In the following case history a neglected callus led to a gas gangrene infection. Coupled with the diabetic neuropathy was an obstruction to the superficial femoral artery (Figure 1) which devascularized the foot to a certain extent, thus aiding the development of infection.

Case History

A 51-year-old female with a twenty-year history of diabetes developed a draining ulcer in a callus on the ball of her right foot. Two days prior to admission on November 20, 1964, she developed pain, swelling, and redness over the dorsum of the foot.

She was admitted to Swedish Hospital where she was found to be frebrile, with obvious crepitation over the foot. An x-ray showed gas formation. Cultures grew out E. coli and coagulase negative staphylococci. She was placed on large doses of penicillin and chloramphenicol and on November 21, 1964, an extensive debridement was carried out revealing black necrotic tissue.

During the first few postoperative days the general condition of the patient improved but the foot remained in jeopardy. An evaluation of the vascular status of the limb revealed no pulses palpable below the groin. A femoral arteriogram demonstrated a block in the superficial femoral artery but a good-sized popliteal artery with a two-vessel runoff. It was the opinion of the attending surgeon that without improvement in the vascular flow to the foot a below-knee amputation would be required.

On November 3, 1964, a saphenous vein shunt was fashioned to bypass the obstruction in the femoral artery. This was successful and a good pulsation was achieved in the posterior tibial artery at the ankle, with rapid improvement in the circulation of the foot making it possible to perform a transmetatarsal amputation on December 8, 1964.

Discussion

In this instance it was possible to salvage a mid-foot level of amputation in a situation that commonly results in the loss of a limb. The wound healed slowly but completely (Figure 2) and the patient was able to ambulate without difficulty by wearing a special shoe. This became important in her clinical progress, for renal and ophthalmic complications increased and she became essentially blind yet was able to continue to walk. She died of renal failure on March 21, 1967.

It may be asked whether it was not dangerous to perform the revascularization procedure in the face of an open and poorly healing wound. Yet in this

instance, the cellulitis had largely subsided and the administration of systemic antibiotics had cleared all but the immediate foot area of bacteria. Soon after the venous graft had been inserted the circulation of the wound improved, and after a few days it seemed feasible to perform the transmetatarsal amputation since a good posterior tibial pulse could be palpated at the ankle.

The distal foot amputation did not heal as promptly as is usually observed with a below-knee amputation, but healing was eventually complete and the wait was worthwhile, for the patient eventually lost her vision from diabetic retinopathy and ambulation with a higher amputation would have been

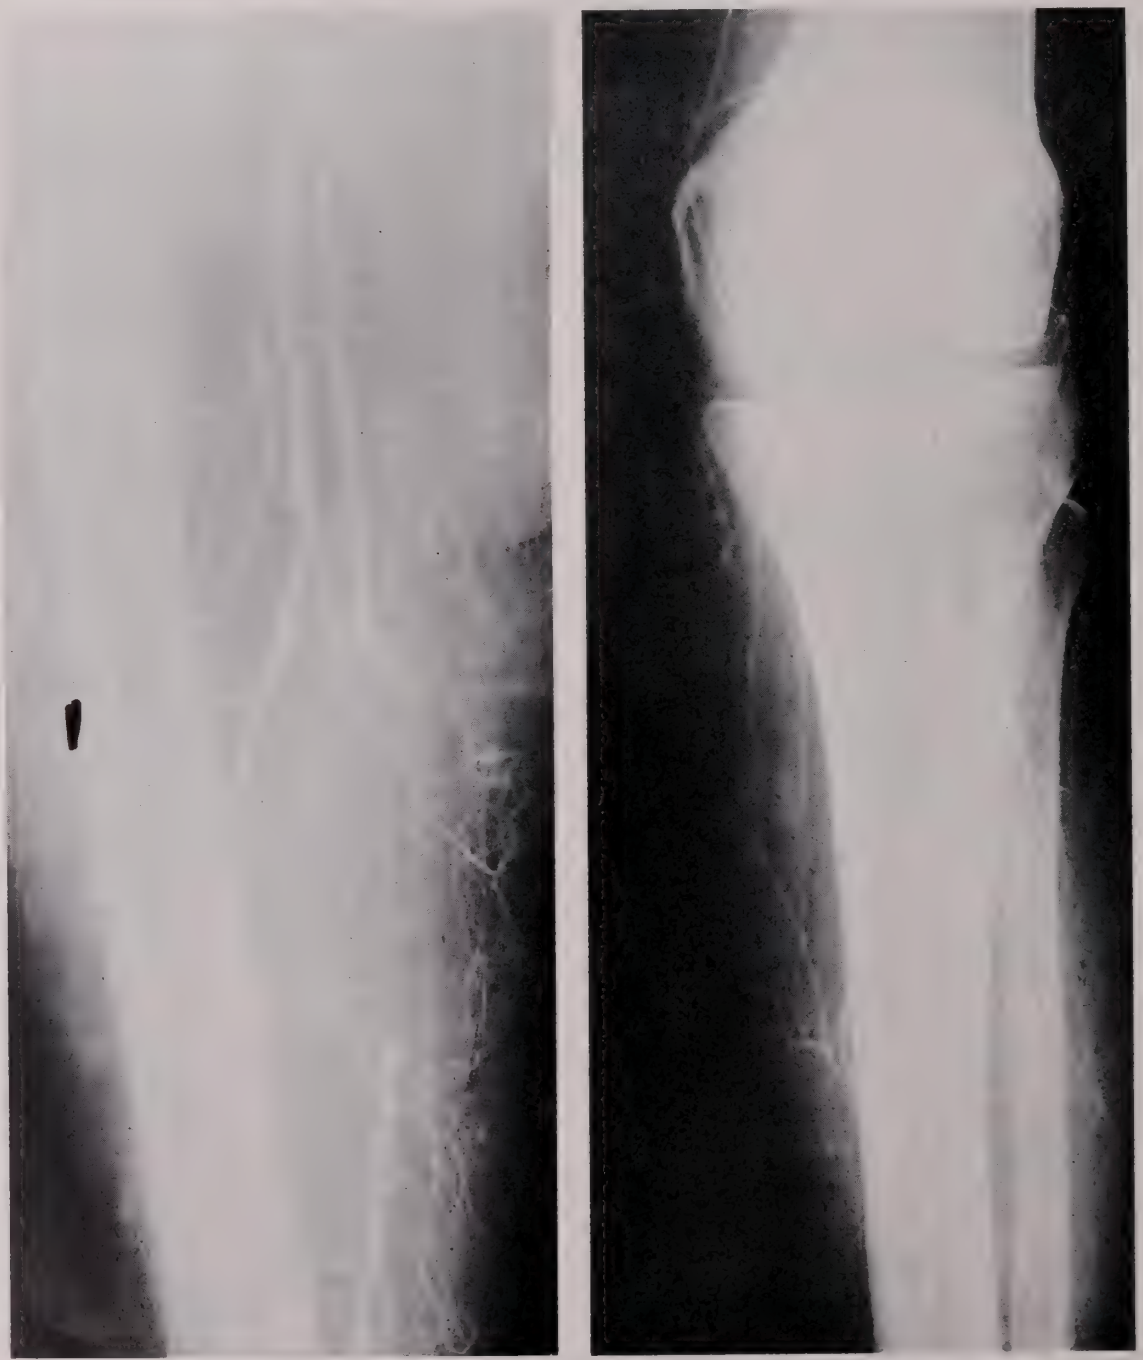

Fig. 1—Arteriogram revealing localized block in superficial femoral artery with good run off.

Fig. 2—Picture showing healed amputation.

much more difficult.

It would have been unthinkable to have inserted a prosthetic graft in this situation; consequently, if a usable vein were not available and the situation would not lend itself to a localized endarterectomy the revascularization procedure would have had to be foregone and a below-knee or above-knee amputation performed as the situation demanded.

The lesson to be learned in this case presentation is that although diabetics are prone to an endarterial disease they also develop arterial obstructive disease at levels that can be bypassed successfully by present-day vascular techniques. Diabetics with peripheral-vascular disease should not be excluded from complete evaluation and arteriograms, simply because they are diabetics.

The potential devastation that may be initiated in a diabetic from a simple callus or minor injury is once again illustrated. Proper and meticulous foot care by careful paring of calluses, the wearing of well fitting shoes, and vigorous treatment of infection should be routine in the physician's management of his diabetic patient.

10-30

Don't use Magan on all your patients–

consider Magan for those patients who cannot take aspirin because of gastric discomfort

Private Practice Physicians tried Magan on almost 700 patients whom they judged intolerant to aspirin and other salicylates.

The majority of these patients could take Magan and obtain the benefit of salicylate therapy.

magan®

an alternate salicylate

(magnesium salicylate, W-T)

May be tolerated by some persons intolerant to aspirin by reason of gastrointestinal irritation.

Magan is a new salicylate product from Warren-Teed.

A single chemical entity . . . no coating, no buffering, sodium free and non-acetylated.

Composition: Each orange colored tablet contains 5 grains (approx. 325 mg) of magnesium salicylate.
Dosage: 1 or 2 tablets every 4 hours with a full glass of water.

Knee-deep

in osteoarthritic pain

If aspirin doesn't help, move in with Tandearil.

The trial period is brief: 1 week. Try one tablet q.i.d. at first. Tandearil usually starts working within 3 to 4 days. When response occurs, as little as 1 or 2 tablets daily may hold back pain and stiffness, and increase joint motion.

On the next page is a summary of adverse reactions, contraindications, warning and precautions.

Tandearil.
It can help get his mind off his knee.

Please review full Prescribing Information carefully before prescribing.

For osteoarthritic knees, spines, shoulders, hips, etc.:

Tandearil®
oxyphenbutazone

Tandearil, oxyphenbutazone:
For brief summary see next page.

Geigy

TA-6006

Tandearil®
oxyphenbutazone

Contraindications: Edema; danger of cardiac decompensation; history or symptoms of peptic ulcer; renal, hepatic or cardiac damage; history of drug allergy; history of blood dyscrasia. The drug should not be given when the patient is senile or when other potent drugs are given concurrently.

Warning: This drug is an analog of phenylbutazone; sensitive patients may be cross-reactive. If coumarin-type anticoagulants are given simultaneously, watch for excessive increase in prothrombin time. Instances of severe bleeding have occurred. Persistent or severe dyspepsia may indicate peptic ulcer; perform upper gastrointestinal x-ray diagnostic tests if drug is continued. Pyrazole compounds may potentiate the pharmacologic action of sulfonylurea, sulfonamide-type agents and insulin. Carefully observe patients receiving such therapy. Use with caution in the first trimester of pregnancy, and in patients with thyroid disease.

Precautions: Before prescribing, carefully select patients, avoiding those responsive to routine measures as well as contraindicated patients. Obtain a detailed history and a complete physical and laboratory examination, including a blood count. The patients should not exceed recommended dosage, should be closely supervised and should be warned to discontinue the drug and report immediately if fever, sore throat, or mouth lesions (symptoms of blood dyscrasia), sudden weight gain (water retention), skin reactions, black or tarry stools or other evidence of intestinal hemorrhage occur. Make complete blood counts at weekly intervals during early therapy and at 2-week intervals thereafter. Discontinue the drug immediately and institute countermeasures if the white count changes significantly, granulocytes decrease, or immature forms appear. Use greater care in the elderly and in hypertensives.

Adverse Reactions: The more common are nausea and edema. Swelling of the ankles or face may be minimized by withholding dietary salt, reduction in dosage or use of diuretics. In elderly patients and in those with hypertension, the drug should be discontinued with the appearance of edema. The drug has been associated with peptic ulcer and may reactivate a latent peptic ulcer. The patient should be instructed to take doses immediately after meals or with milk to minimize gastric upset. Drug rash occasionally occurs. If it does, promptly discontinue the drug. Agranulocytosis, exfoliative dermatitis, Stevens-Johnson syndrome, Lyell's syndrome (toxic necrotizing epidermolysis), or a generalized allergic reaction similar to a serum sickness syndrome may occur and require permanent withdrawal of medication. Agranulocytosis can occur suddenly in spite of regular, repeated normal white counts. Stomatitis, salivary gland enlargement, vomiting, vertigo and languor may occur. Leukemia and leukemoid reactions have been reported. While not definitely attributable to the drug, a causal relationship cannot be excluded. Thrombocytopenic purpura and aplastic anemia may occur. Confusional states, agitation, headache, blurred vision, optic neuritis and transient hearing loss have been reported, as have hyperglycemia, hepatitis, jaundice, hypersensitivity angiitis, pericarditis and several cases of anuria and hematuria. With long-term use, reversible thyroid hyperplasia may occur infrequently. Moderate lowering of the red cell count due to hemodilution may occur.

Dosage in Osteoarthritis: Initial: 3 to 6 tablets daily in divided doses. Usually unnecessary to exceed 4 tablets daily. A trial period of one week is considered adequate to determine the therapeutic effect of the drug. Maintenance: Effective level often achieved with 1 or 2 tablets daily, should not exceed 4 tablets daily.

In selecting appropriate dosage in any specific case, consideration should be given to the patient's weight, general health, age and any other factors influencing drug response.

Availability: Tan, round, sugar-coated tablets of 100 mg. in bottles of 100 and 1000.

Dermatology

Diabetes Mellitus Cutaneous Manifestations

CUTANEOUS ABNORMALITIES associated with diabetes mellitus are varied and classification is difficult. Some are generalized (bronzing); others are localized (mal perforant). A few disorders occur where diabetes may be suspected but cannot always be proved (necrobiosis lipoidica). These dermatoses should be kept in mind for they may provide a diagnostic clue.

General Changes

Cutaneous abnormalities in diabetics may be due to dehydration (dryness of the skin and mucous membranes). Dryness may be associated with scaling and pruritus. Itching sometimes occurs without dryness. When severe and prolonged, pruritus leads to excoriation, infection, and eczematization.

Disorders of pigmentation are also associated with diabetes. Three types occur: (1) diffuse bronzing similar to that in Addison's disease due to an increased supply of melanocyte stimulating hormone, and (2) xanthochromia resembling icterus as a result of decreased ability to convert carotene to vitamin A in the liver. Xanthochromia is most intense on the palms, soles, forehead, nasolabial grooves, behind the ears, and over the knuckles. It does not involve the scleras, thus differentiating it from jaundice. (3) Slate-blue pigmentation with hemochromatosis. Sometimes in the latter diffuse bronzing secondary to the deposition of melanin is associated.

Infection

Diabetics have increased susceptibility to both bacterial and fungal infections. Candidiasis is common in diabetics. It frequently involves the anogenital region, although other intertriginous areas and the oral cavity may be affected. Systemic involvement is rare, but when it occurs the prognosis is grave. Candidiasis may be the presenting complaint in a patient with chemically unproved diabetes. This is important. Once diabetes is controlled cutaneous candidiasis can be eradicated by use of various nystatin preparations. Amphotericin B intravenously has been employed in the treatment of the systemic form of the disease. It is seldom curative.

Furuncles and carbuncles occur frequently in diabetics. Control of diabetes plus specific measures directed toward the infection are usually effective. These lesions may recur in spite of adequate control of the underlying disorder.

Trophic Disturbances

Circulatory impairment may lead to recalcitrant ulcerations on the soles as well as the ankles. On the soles the process usually begins as a hyperkeratotic area on the ball of the foot. Later the lesion becomes soft, moist, and painful. Eventually an indolent, necrotic ulcer develops (mal perforant). Degenerative changes in nerve terminals may play a causative role.

Any ulcer, whether trophic or traumatic, may lead to gangrene in the

diabetic. Other factors include neglect of the feet, dermatophytosis, and other infections. Gangrene frequently involves the toes, though any part of the body can be affected. Treatment is both medical and surgical.

Xanthoma Diabeticorum

Hyperlipemia secondary to diabetes may be associated with xanthomas. The eruption is characterized by multiple, small, brownish-yellow papules, nodules, and plaques. The lesions occur in crops. At times the disorder causes intense pruritus resulting in excoriations. Extensor surfaces, palms, and soles are frequently affected. There is hyperlipemia, especially elevation of neutral fat. A cloudy serum results. The lipid and cholesterol values of the serum return to normal and the eruption usually disappears after the diabetes is controlled.

Acanthosis Nigricans

In this disorder there are hyperpigmented, verrucous plaques involving the axillas, neck, genital and submammary regions, or any of the large flexor surfaces. The association of acanthosis nigricans with internal malignancy has been stressed when onset is in adult life. The disorder can also be associated with various endocrinologic abnormalities including diabetes mellitus. Whether this association is primary or merely a result of obesity accompanying many of the endocrine disturbances is unknown.

Lipodystrophy and Lipoatrophy

A rare group of disorders characterized by disappearance of the subcutaneous fat is included here. Bony projections, muscles, and vessels become prominent. Progressive lipodystrophy usually has a cephalothoracic progression with cessation of the process at the iliums. An increased incidence of diabetes mellitus and hyperlipemia has been reported in the disorder. Lipoatrophic diabetes may or may not be related to progressive lipodystrophy. Lipodystrophy is generalized in this type of the disease. Hyperglycemia (resistant to insulin), hyperlipemia, and accumulation of fat in the liver with ensuing cirrhosis have also been observed.

Necrobiosis Lipoidica

This disorder is characterized by yellowish-red, irregular, round, or oval plaques with sharp borders. The central portion of the lesion is atrophic. Telangiectases occur peripherally. There may be scaling, and rarely ulceration. The lower legs are affected usually, although lesions may be present on the trunk and upper extremities. Necrobiosis lipoidica occurs in patients who have chemically proved diabetes mellitus. There are cases, however, in which the glucose tolerance test is normal. Histochemical studies usually show changes in these lesions similar to those in other diabetic microangiopathies. Treatment of the disorder is unsatisfactory.

Dermopathy

Localized pigmentary changes in diabetics have been reported recently. In these patients brown macules occur on the pretibial areas, varying in size from 1.0 to 3.0 cm in diameter. Atrophic areas may be associated. Pigmentation is apparently due to hemosiderin. Microangiopathy is present as in necrobiosis lipoidica.

Iatrogenic

The dermatologic complications arising from diabetic therapy are included here. Hypoglycemic sulfonamides may be associated with allergic reactions as well as an ill-defined paroxysmal vasomotor erythema. The former are most frequent and consist of pruritus, erythema, purpura, urticaria, and occasionally vesicles or bullae. The reactions may occur any time, but usually from one to three weeks following the institution of treatment. These reactions are probably allergic, although cutaneous tests have been unsatisfactory.

Complications arising from insulin therapy range from allergic reactions to lipodystrophies. The former are probably due to impurities, protamine, phenol, and zinc. The latter are more important and occur most frequently in adult women following injection of insulin. Their onset is usually within five years after treatment with insulin has been instituted. Lipodystrophy occurs in two forms: hypertrophic and atrophic. The hypertrophic type resembles lipoma microscopically. The lesions sometimes regress spontaneously or may undergo involution following infiltrations of hyaluronidase of hydrocortisone. The atrophic form occurs as depressed plaques varying in size from one to several centimeters. No spontaneous regression occurs in this type. Prophylactic measures are helpful (rotation of sites of injection).

Conclusion

The recognition of dermatoses associated with diabetes mellitus is important in the diagnosis of the disease as well as the so-called prediabetic state. Unfortunately, most of these manifestions are resistant to treatment.

Willard C. Peterson, Jr., M.D.*
Minneapolis, Minnesota

*Division of Dermatology, University of Minnesota Medical School, Minneapolis.

Greek vs. Christian

The Greek world exalted the healthy and sound and considered disease the sign of an inferior being. In the Christian world there was a definite tendency to glorify suffering and to look up to the sick and suffering man as to a superior being. Christ crucified, through his agony and death, had redeemed the world. Whoever suffered was carrying the Cross in the footsteps of his Master. Suffering was interpreted as an ordeal and whoever stood the test without rebellion could expect to be rewarded in the hereafter. The story of the righteous Job suffering unrighteously, rebelling but then humbling himself and submitting to God, acquired increased significance. In Christianity *Pathos* became *Ethos*. Suffering was a sign of grace, not to be evaded but sought.*

"Upper respiratory infection! I thought everything was a 'virus' these days?"

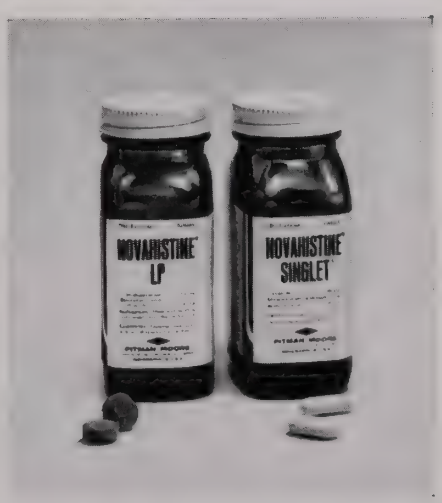
Some U.R.I. patients are more miserable than others.

That's why we make Novahistine® tablets in two different formulations.

And let you control the dosage.

With Novahistine LP tablets and Novahistine Singlet tablets you have the range and flexibility of decongestant dosage that lets you prescribe for the needs of the individual patient.

Novahistine LP tablets are most useful for relief of nasal congestion in patients without pain or fever.



Novahistine Singlet tablets, which provide analgesic-antipyretic effect, as well as decongestant action, are indicated for upper respiratory infections accompanied by pain, aches and fever.

Whether you prescribe Novahistine LP or Novahistine Singlet, a total daily dose of 3 or 4 tablets will usually provide effective, continuous relief.

Use cautiously in patients with severe hypertension, diabetes mellitus, hyperthyroidism or urinary retention. Caution ambulatory patients that drowsiness may result.

Each Novahistine LP tablet contains phenylephrine hydrochloride, 25 mg.; and chlorpheniramine maleate, 4 mg.

Each Novahistine Singlet tablet contains phenylephrine hydrochloride, 40 mg.; chlorpheniramine maleate, 8 mg.; and acetaminophen, 500 mg.

Effectiveness: ACHROMYCIN Tetracycline is a crystalline broad-spectrum antibiotic which provides effective therapeutic activity against susceptible microorganisms.

Contraindication: History of hypersensitivity to tetracycline.

Warning: In renal impairment, usual doses may lead to excessive accumulation and liver toxicity. Under such conditions, lower than usual doses are indicated and, if therapy is prolonged, serum level determinations may be advisable. Some patients may develop a photodynamic reaction to natural or artificial sunlight. Those with a history of photosensitivity reactions should avoid direct exposure to sunlight while under treatment. Discontinue drug at first evidence of skin discomfort.

Precautions: Use may result in overgrowth of nonsusceptible organisms. Constant observation is essential. If new infections appear, take appropriate measures. Use of tetracycline during teeth development may cause discoloration of teeth.

Side Effects: Gastrointestinal system—anorexia, nausea, vomiting, diarrhea, stomatitis, glossitis, enterocolitis, pruritus ani. Skin—maculopapular and erythematous rashes (a case of exfoliative dermatitis has been reported); photosensitivity reaction, onycholysis and discoloration of nails (rare). Kidney—rise in BUN, apparently dose-related. Hypersensitivity reactions—urticaria, angioneurotic edema, anaphylaxis. In young infants, bulging fontanels have been reported following full therapeutic dosage. This symptom has disappeared rapidly when drug is discontinued. Teeth—dental staining (yellow-brown) in children of mothers given tetracycline during the latter half of pregnancy, and in children given the drug during the neonatal period, infancy and early childhood. Enamel hypoplasia has been seen in a few children. Blood—anemia, thrombocytopenic purpura, neutropenia, eosinophilia. Liver—cholestasis (rare), usually at high dosage. Tetracycline may form a stable calcium complex in bone-forming tissue. If adverse reaction or idiosyncrasy occurs, discontinue medication and institute appropriate therapy.

Average Adult Daily Dosage: One Gm. per day, in 4 divided doses of 250 mg. each. Should be given 1 hour before or 2 hours after meals, since absorption is impaired by the concomitant administration of high calcium content drugs, foods and some dairy products. Treatment of streptococcal infections should continue for 10 days, even though symptoms have subsided.

ACHROMYCIN® WORKS HERE
TETRACYCLINE

Actually ACHROMYCIN works wherever the infection is due to an organism your lab cultures have shown to be tetracycline-sensitive. No other tetracycline—or analogue—can assure you of quicker or more effective antibiotic action. After all, isn't that what you want for your patient?

ACHROMYCIN was a pioneer in tetracycline therapy. Seventeen years of experience have shown that when the respiratory system, the genitourinary system, or the skin and soft tissue require treatment for infection probably caused by any of a number of sensitive strains, ACHROMYCIN is a wise choice for therapy while awaiting test results.

Available in 31 useful forms to meet your situational needs.

Clinical Path Conference

Diabetes and Infection

Calvin Bandt, M.D.:*

First Hospital Admission

A 64-YEAR-OLD white woman was admitted because of rectal bleeding. A rectal mass lesion was discovered and biopsied and found to be an infiltrating adenocarcinoma. Physical examination was otherwise normal except for obesity and a large ventral hernia. The patient had been known to have diabetes mellitus for some years, but this was reasonably well controlled with tolbutamide, 1.5 grams daily.

On the 15th hospital day the patient underwent an extensive combined abdominoperineal resection of the rectal carcinoma and the contiguous lymph nodes which were involved with the tumor. This operation included a panhysterectomy and total excision of the vagina as well as repair of the large ventral abdominal hernia.

Postoperative Infection

Her postoperative course was complicated by an extensive wound infection with coliform organisms; episodes of congestive heart failure, atrial arrhythmias and digitalis intoxication; the development of a persistent urinary tract infection with, at first, Aerobacter and subsequently Pseudomonas organisms; and at least one episode of apparent gram-negative septicemia. Incision, drainage and irrigation of the wound, with intensive antimicrobial chemotherapy (including courses of cephalothin, penicillin, chloramphenicol, streptomycin, nitrofurantoin, mandelamine, and colistin) finally succeeded in healing the surgical wound but failed to eradicate the urinary tract infection. Insulin was used to control her diabetes during the immediate operative interval, but thereafter tolbutamide was again instituted. Three weeks prior to her discharge, the patient developed a rather prolonged hypoglycemic reaction and the tolbutamide was withdrawn. It was not reinstituted.

Laboratory Studies

After 133 hospital days the patient was discharged. At that time her hemoglobin was 13.4 grams, her white blood count 19,500 with 85% neutrophils. Urinalysis disclosed a specific gravity of 1.010, 2+ albumin, a trace of sugar, occasional red blood cells and 200 white blood cells per high power field. Fasting blood glucose was 267, blood urea nitrogen was 40 mg% and serum electrolytes were normal. Urine culture produced over 100,000 colonies of Monilia, alpha streptococci, Proteus and approximately 50,000 colonies of Staphylococcus aureus and Pseudomonas. The Pseudomonas was sensitive only to colistin and polymixin B. The patient was given a prescription for mandelamine, 2 grams daily and vitamin capsules.

Second Hospital Admission

Four days after discharge the patient was admitted to the Neurology Service with coma and right-sided focal motor seizures. Because of hypotension she was given metaraminol 10 mg and lanatoside-C 0.8 mg in the ambulance en route to the hospital.

*Associate Pathologist, Hennepin County General Hospital, Minneapolis.

Admission physical examination revealed a blood pressure of 100/60, a pulse of 100 and irregular, respirations 30 and deep and full. The rectal temperature was 103 degrees. The patient was deeply stuporous, responding to painful stimuli with only slight movement in the extremities . Tendon reflexes were hypoactive. The Babinski sign was questionably positive on the right. Her breath was noted to be sweet. The abdominal wounds were open and draining material with an odor thought by the examiner to be characteristic of Pseudomonas. There was a new open, macerated lesion over the sacrum. The skin was dry, and bluish mottling was observed on the legs and arms. Lymphedema was present in both lower extremities. The lungs were found to be normal and the heart was normal except for frequent premature beats.

Laboratory Studies

The hemoglobin was 11.6, white blood count 33,200 with 93% neutrophils. Urinalysis showed a specific gravity of 1.012, 1+ albumin, 4+ sugar, red blood cells packed field, white blood cells packed field. The blood glucose was 1,182 mg%, BUN 113 mg%, blood pH 7.33, serum acetone positive, sodium 130 mEq.L, potassium 3.8 mEq/L, chloride 85 mEq/L, and CO_2 15 mEq/L. Culture of the urine disclosed over 100,000 colonies of a mixture of gram-negative rods including Proteus and Pseudomonas. These organisms as well as a coagulase positive Staphylococcus aureus were also recovered from the abdominal wound. Electrocardiogram was normal except for premature atrial and ventricular contractions. Chest roentgenogram disclosed no abnormalities.

Treatment

The patient was given an infusion of 1,000 cc of normal saline with 12.5 grams of mannitol, followed by 1,000 cc of dextrose in normal saline. Thereafter she was given continuous infusions of 5% dextrose in water with additional potassium chloride and sodium chloride. A summary of her fluid and electrolyte therapy is appended at the end of this protocol (Table). Fifty units of regular insulin was administered subcutaneously on admission, and she was given insulin according to her urine glucose in a dose of 20 units for 4+, 15 units for 3+, 10 units for 2+, and 5 units for 1+. One gram of chloramphenical was given immediately and thereafter 500 mg IM every eight hours.

TABLE

Fluid and Electrolyte Therapy

Hospital Day	Fluid	Electrolytes		Urine Output
1 (12 hours)	4000 cc	Mannitol	12.5 gm	2060
		KCl	140 meq	
		NaCl	300 meq	
2	4000 cc	KCl	56 meq	824
		NaCl	170 meq	
3	5400 cc	KCl	100 meq	875
		NaCl	350 meq	

Shortly after admission she was transferred to the Medicine Service, where this treatment program was continued. During the next 48 hours her level of consciousness improved slightly and she was observed to be moving in bed and moaning. No further seizures were observed. Twenty-four hours after admission urine glucose was negative although blood glucose at the same time was 500 mg%. Serum acetone became negative and remained so. The patient received 70 units of regular insulin on the first hospital day, 60 on the second and 55 on the third. On the third day serum sodium was 128 mEq/L, potassium 5.4, chloride 100, CO_2 16 mEq/L. BUN was 92 mg%. A lumbar puncture was performed and examination of the cerebral spinal fluid was normal.

Late on the third hospital day the patient was transferred to the Surgery Service. Little change in her condition was observed until 12 hours later when she abruptly developed respiratory distress and became hypotensive and "ashen" in color despite oxygen administration. Her blood pressure then became unobtainable and she ceased breathing. Resuscitation was unsuccessful. Blood cultures obtained on admission became positive for Pseudomonas on the day the patient died. An autopsy was performed.

Clinical Discussion

Robert Maslansky, M.D.:*

This protocol describes the course of events in over 100 days of hospitalization, and for all practical purposes I think the four-day absence may be disregarded. The entire course can be viewed as one hospital admission for a patient who comes in for treatment for carcinoma and ultimately dies. Among other pertinent facts is her dying a septic death. There were enough organisms in her to account for several foci of infection. Having said this we have to ask: where did this sepsis begin and where did it finally end? As for whence it came, I suspect that in a diabetic with this type of problem, the logical organ is the kidney, especially since we see in the earliest part of the protocol that she had regional lymph nodes involved with a virulent cancer. One wonders whether there might have been dissemination of this malignancy into the abdominal viscera and possibly metastases to her brain to account for the focal findings and lateralizing signs which were evident on the final admission. I must confess that I do not consider this a likely possibility, as it is improbable that this would occur so rapidly.

Diabetes and Arterial Disease

Now some thoughts about her diabetes. She is what has to be considered an insulin-dependent diabetic. We do not know how many years she has been diabetic, but I think it is fair to state that in diabetes over 20 years in duration, in spite of the age of onset, there is a one out of two chances of her having significant arterial degenerative disease, both in the small vessels, with retinal arteriole involvement, as well as in the medium-sized vessels, including the coronary arteries. I think the data from the literature supports this; and if we can assume this lady has been diabetic for some years, then we must assume that she has significant arterial disease. However, the dynamics of her diabetes changes appreciably when she becomes stressed, and she has undergone stress, first of all with her cancer (presumably by bleeding) and secondly with a major mutilative surgical procedure.

Diabetes and Surgery

I have a reference that is of some considerable interest to anyone who is considering operating on diabetics. It is the most definitive survey of diabetes in surgery that I know of: a study of 667 cases. I would like to read directly from the summary and conclusions. "A detailed analysis of the course of 487 diabetic patients who underwent 667 surgical procedures is presented. Twenty-three percent of the patients in the series were found to be diabetic either before surgery (100 instances) or during their surgical admission (12 instances). It is concluded that diabetes is frequently first discovered on the surgical services of general hospitals. Arteriosclerosis of all forms was present in thirty percent of the patients and accounted for twenty-nine percent of the deaths. Infection was the greatest hazard of the diabetic surgical patient, being the cause of eighty percent of the emergency operations, and accounting for eighty percent of the surgical complications and seventy-five percent of the nonsurgical complications. Ninety percent of the patients with diabetic nephropathy, who had surgery during the period of study, were beset with septic complications."† I think the salient point is that operating on a diabetic, insulin-dependent or independent, is considerably more risky than operating on a non-diabetic, particularly with regard to sepsis.

---

*Clinical Assistant Professor of Medicine, University of Minnesota, Minneapolis.

Renal Disease

It is tempting to consider diabetic acidosis part of the patient's problem during her last days; however, I doubt that. What I think happened was that the kidney had simply given up fighting a life-long battle of acidosis. It was just not sufficiently there to provide the internal milieu with a buffer against the acidosis. What we are dealing with is doubtless renal acidosis.

This is borne out by a blood urea nitrogen of 113 mg%. The reason the kidneys failed is because they were missing some parts, namely, the papillae. This is a presumption on my part, but I think I am coming right to the heart of the problem when I say that I believe this patient had necrotizing renal papillitis, sometimes called renal medullary necrosis, though at no point in the protocol is it indicated that a definitive diagnostic test was done. Renal papillitis is a diagnosis readily arrived at in circumstances like this, if one can microscopically visualize papillae in the urine. This is usually most effectively done by having the urine strained through a piece of cheesecloth. On two occasions I have seen papillae in the urine when this was done. According to the literature on renal papillitis the papillae are sometimes missed because they are too small or fragmented.

Glucose Clearance

Lastly, with respect to renal lesions, one wonders about Kimmelstiel-Wilson's disease, perinephric abscess, or simple pyelonephritis. My impression from the protocol is that the flow of events was entirely too staccato. There was not simply a downhill course from the time of initial surgery to her death; rather there were periods of remission and exacerbation which terminated in the catalysmic event with the acidosis, azotemia and ventricular fibrillation. Now there is one little loose end I want to wrap up. That is the paradox of 500 mg% of sugar associated with no glycosuria. I do not know what happens to glucose clearance when the papillae are gone. I must confess that after some review I could find no literature on the subject. But my surmise is that the threshold goes up, and perhaps this is the circumstance that prevailed here: that though she had 500 mg% of sugar in the blood, the kidneys were just not clearing it.

I think this woman had necrotizing renal papillitis and that she was septic. I believe she had an adenocarcinoma of the rectum with metastases to the regional lymph nodes. In addition she had diabetes mellitus of the adult onset type; and she probably had a small amount of coronary artery disease, besides, along with cerebral arteriosclerotic degenerative disease. This is where I am going to stop.

Clinical Diagnoses

1. Diabetes mellitus of adult onset.
2. Necrotizing renal papillitis.
3. Sepsis
4. Metastatic adenocarcinoma of the rectum
5. Coronary and cerebral arteriosclerosis

Pathologic Findings

Dr. Bandt:

I will preface the pathological discussion by saying that we have a somewhat incomplete autopsy; we were excluded from examining the brain at

the request of the family. Consequently, the etiology of her neurologic problems which precipitated the final admission is not known.

External examination showed bilateral lower extremity edema and thrombosis of both saphenous veins. Both the abdominal and perineal wounds were opened and drained, with granulation tissue and no evidence of any lobulated abscess. The heart weighed 430 grams and was enlarged. The coronary arteries showed no significant coronary artery atherosclerosis; but on subsequent microscopic examinations there was moderate to severe involvement of the small coronary vessels. In addition, there was some patchy myocardial fibrosis.

Pulmonary Pathology

The left lung weighed 230 grams, the right lung 400 grams. The lung pathology was largely confined to the right lower lobe and particularly the posterior basal portion, which was very dense without crepitus and very hemorrhagic. Along one edge, the part lying in the costophrenic angle was very yellow and soft, with a fibrous membrane around the outside of this area which, on sectioning, contained material that appeared to be an abscess. In the segmental artery to this area of the lung there was found an organizing thrombus, and the microscopic sections of this vessel showed an already well organized thrombus which had partially recanalized. This thrombus is of some age and corresponds in time with the episode of thromboembolism earlier in her hospital course. The surrounding lung was very necrotic and showed a complete loss of cellular detail with no inflammatory infiltrate. However, near this infarct there is some inflammation representing a pneumonia: probably a Pseudomonas pneumonia in combination with the old resolving pulmonary infarct. The organism is in part presumptive and determined from the fact that she had Pseudomonas growing from her sputum.

Sections from the spleen and liver showed small calcified nodules measuring up to 1 mm in diameter; these are old granulomas, with the most likely etiology of histoplasmosis, which has become completely calcified. Section of the pancreas showed a moderate number of hyalinized or partially hyalinized islets, which are compatible with the type of hyalinization seen in the adult onset type of diabetes.

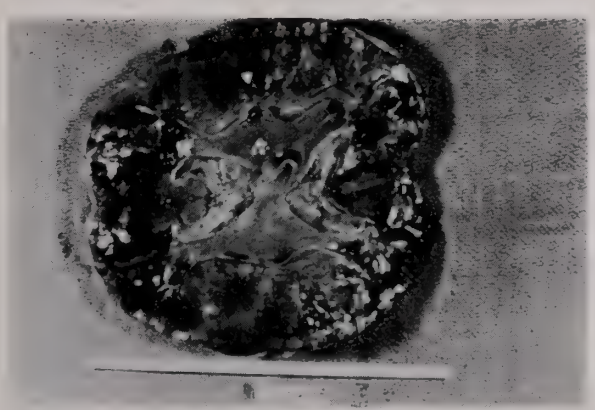

Fig. 1.—Kidney showing hemorrhage and infarction of papillae and pale areas of abscesses in cortex.

Kidney Pathology

The left kidney weighed 360 grams and the right 260 grams. Both pelvis and ureters were slightly dilated. The capsules stripped with difficulty and the cortex was very pale and soft. On section there were multiple pale yellow miliary areas throughout both the cortex and medulla. In addition, both kidneys showed a near total *loss of all the renal papillae* with necrosis of the remaining medullary portion near the papillae. As Dr. Maslansky said, this is the hallmark of necrotizing renal papillitis. Microscopic section through the remainder of one of these papillae shows that the parenchyma is completely necrotic. In addition, there are large masses of inflammatory cells, most of which are neutrophils, representing *small microabscesses* (Figure 1).

A Gram's stain done on this tissue showed numerous small organisms approximately the size of a red blood cell, with the typical budding forms of a yeast. These are a species of Candida, probably Candida albicans. In addition to the yeast forms, in other areas we were able to find the pseudohyphae form of the Candida organism. Other areas from the same block of tissue show large clumps of gram-positive cocci which are growing in clusters and appear to be Staphylococcus aureus. The gram-negative organisms which we presume to be there from the urine cultures and other data did not show up well enough on the Gram's stain for us to be able to say they were definitely there.

The glomeruli show early *intercapillary glomerulosclerosis* typical of diabetes mellitus; however, this is so minimal that it would not cause uremia by itself. This is supported by the fact that she had a normal BUN when first admitted. There also was some early hyalinization of afferent and efferent glomerular arterioles.

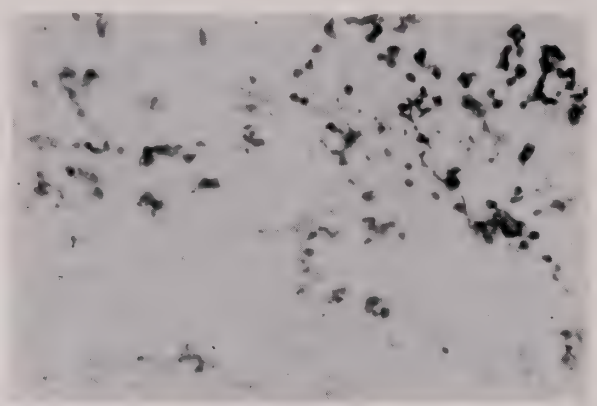

Fig. 2—Gram's stain (X430). From renal papilla, with necrotic material and pseudohyphae of Candida species.

Pseudomonas Septicemia

The relationship of the Pseudomonas septicemia to the necrotizing renal papillitis is still unclear. Normally Pseudomonas has very little talent for invasion and is usually seen in patients who are debilitated—with diabetes, burns, or lymphomas. Thus, the possibility that Pseudomonas is an agonal infection may be true in this case. The fact that she did not show gram-negative shock as a clinical picture is not too unusual, because Pseudomonas does not have the potential to produce gram-negative shock in the same manner that organisms such as Aerobacter and E. coli do. In only about 10% of the cases of Pseudomonas septicemia is there a true picture of gram-negative shock.

There is one other interesting aspect of Pseudomonas septicemia in that it has also been reported as causing a syndrome of disorientation, coma and convulsions. It is interesting to speculate that the Pseudomonas grown from her blood shortly after admission may have been the etiology of this. However, there is no proof.

Candida also has very little potential for invasion; but in debilitated patients such as diabetics it will cause true infection. I think this is the case here because we actually have true invasion of the tissue by the organism.

The etiology of necrotizing renal papillitis is not known, but it is usually associated with pyelonephritis. The organism may be quite variable and is not associated with a vasculitis. Part of the etiology in this case may have been the hydronephrosis which was evidenced by the dilated pelvis and ureters. Experimentally, ligature of the ureters and subsequent infection of the urine will produce a necrotizing papillitis in animals. This patient probably had this hydronephrosis as a result of her radical surgery with some injury to the terminal ureters, and this may have been contributory to the final outcome.

The portal of entry for the septicemia is unknown, but there were multiple sources with a pyelonephritis, pneumonia and wound infection.

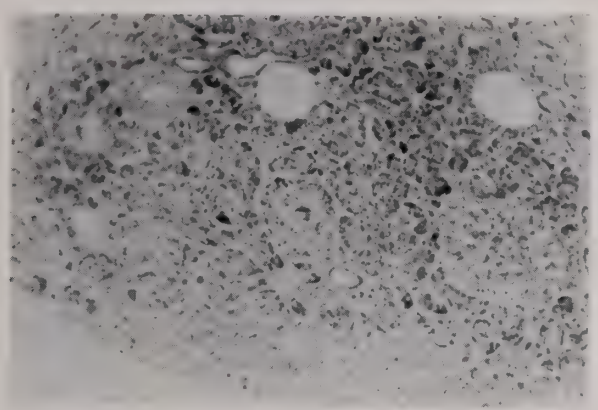

Fig. 3—Pancreas (X100). The islet in the center of the field has been largely replaced by hyaline material.

Pathological Diagnoses

1. Diabetes mellitus, adult type.
2. Bilateral necrotizing renal papillitis and pyelonephritis, probably due to Staphylococcus, Candida albicans and Pseudomonas.
3. Right lower lobe pneumonia probably due to Pseudomonas.
4. Resolving pulmonary infarct, right lower lobe.
5. Early intercapillary glomerulosclerosis.
6. Status postoperative for adenocarcinoma of the colon with no evidence of residual tumor.

Calvin Bandt, M.D.
Hennepin County General Hospital

Men will wrangle for religion; write for it; fight for it; die for it; anything but live for it.—Charles Colton

Nature to the Rescue

Appendicitis

The operations of Nature often seem very stupid. Even the despised tapeworm is congenitally better off than we are. Any segment below the head can be devoured or destroyed, and it can reproduce itself without the aid of an intellect. The snake throws its venom into us and we die; the snake lives to carry more venom. A mosquito jabs us with malaria, yellow fever, and perhaps other undiscovered death-dealing germs, and we die; the mosquito thrives on the deadly poison.

Yet, at other times, Nature will accomplish, unaided, cures more miraculous than any we have ever dreamed of. Frequently, in operating upon other organs of the abdomen, one will find that Nature has performed a surgical operation resulting in the cure of the most fatal type of appendicitis—the like of which is far beyond the power of man even to attempt. Georgia, a student at the University of Wisconsin, was brought to the hospital with an injury demanding surgical intervention. According to the usual routine, I looked for the appendix when I had completed my work in the abdomen. The appendix had left its location and had wandered off in the direction of the gall bladder. Tracing its course, I found it to be neatly enveloped in peritoneal tissue, which formed a canal ending in the intestine six inches from its beginning. It had taken a perfect short route, or bypass, from one intestine to another.

Neither she nor her parents could give me a typical history of a ruptured appendix, but they did remember that when she was quite young, during one of her stomach upsets, the doctor had thought she had colitis—a convenient term, which in those days usually meant ignorance of the true cause of illness. It was probably a ruptured appendix; and, in the face of a fulminating infection, Nature had burrowed—or, rather, constructed a canal toward a less vulnerable site—and had bored a hole through to the large intestine (more resistant to infection than the small intestine), thereby saving Georgia's life.*

*Joseph A. Jerger, M.D.: Doctor, Here's Your Hat!, 1939.

THE PERENNIAL PRONENESS

The respectable medical historian, Fielding H. Garrison, referred to a "fetishistic instinct," a "primitive craving for the supernatural which is ever latent in man." This craving he saw as a common aspect underlying primitive medicine and modern quackery . . . Rabbits' feet afford a steady market in America, at prices ranging from a dime to five dollars. Charms, voodoo bags, and love potions have been said to bring in a million dollars a year from residents of Alabama, Mississippi, and Louisiana alone. And a Missouri root doctor found customers for three magical remedies, a cathartic, an emetic, and—as he called the third—a "rank pizen," all made from the very same root. Hibobalorum was prepared by peeling the bark downward, Lobobahirum by peeling it upward, and Hi-lo-bustem by peeling it around.*

*James Harvey Young: The Medical Messiahs, 1967.

Thinking is more interesting than knowing, but less interesting than looking.
—Goethe

A once-popular treatment for back pains was to have the seventh son of a seventh son stand or walk on the patient's back.

The pain of earache was allegedly relieved by holding a hot roasted onion to the ear.

For headache, a sovereign remedy was to wear a snakeskin round one's head.

A realistic approach to pain relief

Therapeutic breakthrough in non-narcotic control of the pain of

Tegretol®
carbamazepine

trigeminal neuralgia

Warning
Fatal cases of aplastic anemia have been reported following treatment with Tegretol. Agranulocytosis, thrombocytopenia and transitory leukopenia have also been observed.
Complete blood and platelet counts should be done prior to and at regular intervals during treatment with the drug (see recommendations under "Important Note and Precautions") to help in the early detection of serious bone marrow injury. Abnormalities in initial blood tests should rule out use of the drug. Also, patients should be made aware of such early toxic signs of a potential hematologic problem as fever, sore throat, mouth ulcers, easy bruising and petechial or purpuric hemorrhage. Should such signs appear, the patient should be advised to discontinue the drug and to report to the physician immediately.

Indication Tegretol is indicated in the treatment of the pain associated with true trigeminal neuralgia. It is not a simple analgesic and should never be administered for relief of trivial facial aches or pains.
Contraindication Do not use in those with a known sensitivity to any tricyclic compound or in those being treated with M.A.O.I. agents. As long a period as possible should elapse before using Tegretol in patients who have been treated with M.A.O.I.'s, with a minimum of 7 days. In such cases, initial dosage should be low and the patient's reaction to gradual increments closely observed.
Important Note and Precautions Familiarity with the clinical symptoms which lead to an accurate diagnosis of true trigeminal neuralgia and with the complete prescribing information, careful patient selection, a thorough examination before treatment and close patient supervision throughout the treatment period are essential to the safe and effective use of this drug.
Where feasible, Tegretol should not be used in conjunction with any potent drug which may increase the possibility of toxic reactions.
In pregnancy, the drug should not be prescribed during the first trimester and thereafter only to patients in whom the clinical situation warrants the potential risk. It should not be administered to nursing mothers.
Patients with increased intraocular pressure should be closely observed during treatment with this drug because of its anticholinergic effect.
Because of the drug's relationship to other tricyclic compounds, the possibility of activation of latent psychosis and, in the elderly, of confusion or agitation, should be considered.
Dizziness and drowsiness may occur and patients should be cautioned about the hazards of operating machinery or automobiles and of engaging in other hazardous tasks.
Use cautiously in patients with a history of coronary artery disease, organic heart disease, congestive failure or liver disease.
Before initiating therapy, the following laboratory procedures should be performed:
1. Complete blood and platelet counts which, if abnormal, should rule out the use of the drug.
2. Baseline evaluations of liver function.

During treatment with Tegretol, the following laboratory procedures should be performed:
1. Complete blood and platelet counts should be done at intervals of one week during the first month of drug treatment, every two weeks during the second and third months, and at monthly intervals thereafter for as long as the patient is taking the drug. A trend toward a decreasing white blood cell count should suggest a dosage reduction and more frequent laboratory and clinical evaluations. Should this trend continue, the drug should be discontinued.
2. Liver function tests must be performed at regular intervals during treatment with this drug since liver damage may occur during therapy. The drug should be discontinued immediately in cases of aggravated liver dysfunction or active liver disease.
3. Periodic eye examinations, including slit-lamp, funduscopy and tonometry, are recommended for patients being treated with this drug since many phenothiazines and related drugs have been shown to cause eye changes.
4. Complete urinalysis and BUN should be done on patients treated with Tegretol because of observed renal dysfunction.

Adverse Reactions Dizziness, drowsiness, unsteadiness on the feet, nausea, vomiting, aplastic anemia, transitory leukopenia, agranulocytosis, eosinophilia, leukocytosis, thrombocytopenia, purpura, abnormalities in liver function tests, cholestatic and hepatocellular jaundice, urinary frequency, acute urinary retention, oliguria with elevated blood pressure, albuminuria, glycosuria, elevated BUN, microscopic deposits in the urine, impotence, disturbances of coordination, confusion, headache, fatigue, blurred vision, transient diplopia and oculomotor disturbances, speech disturbances, abnormal involuntary movements, peripheral neuritis and paresthesias, depression with agitation, talkativeness, nystagmus, tinnitus, paralysis and other symptoms of cerebral arterial insufficiency, pruritic and erythematous rashes, urticaria, Stevens-Johnson syndrome, photosensitivity reactions, alterations in skin pigmentation, exfoliative dermatitis, alopecia, diaphoresis, recurrence of thrombophlebitis, erythema multiforme and nodosum, aggravation of disseminated lupus erythematosus, gastric distress, abdominal pain, diarrhea, constipation, anorexia, dryness of the mouth and pharynx, glossitis, stomatitis, fever, chills, adenopathy, lymphadenopathy, aching joints and muscles, leg cramps, conjunctivitis, left ventricular failure, aggravation of hypertension, hypotension, syncope and collapse, edema, aggravation of coronary artery disease and congestive heart failure. (Whether these cardiovascular effects are drug-related is not known. However, some of these complications have resulted in fatalities.) The necessity for discontinuing the drug should be dictated by the gravity and severity of the adverse reactions.
Dosage and Administration The drug should always be taken with meals if possible.
Initial: One-half tablet (100 mg.) b.i.d. on the first day. Thereafter, the dose should be increased in one-half tablet (100 mg.) increments every 12 hours until freedom from pain is achieved. To relieve pain, between 200 mg. and 1200 mg. per 24 hours may be necessary.
Maintenance: Initial control of pain can be maintained in most patients with a dose of 400 mg. to 800 mg. daily. Maintenance doses may range between 200 mg. and 1200 mg. daily.
At least once every 3 months during treatment period attempts should be made to discontinue the drug or to reduce the dose to the minimum effective level.
Availability Round, white, single-scored tablets of 200 mg. in bottles of 100 and 1000. (B)46-820-A

"Had a fine home and family."

TO-5757

.Forlorn"

Had a divorce."
m a real loser,
and so are
he kids."

The loss of marital compatibility results in nearly 500,000 U.S. divorces each year.

Depression characterized by untold guilt feelings, grief and loneliness may follow.

When you diagnose depression, Tofrānil may be indicated for relief.

As maintenance therapy during the active phase of depression, Tofrānil can often help prevent relapse.

The use of Tofrānil in patients receiving M.A.O.I.'s is contraindicated. In patients with cardiovascular disease, thyroid disorders, increased intraocular pressure; in those receiving anticholinergics (including antiparkinsonism agents), thyroid medication or antihypertensive adrenergic neuron-blocking agents; and in those in their first trimester of pregnancy—the special precautions listed in the Prescribing Information should be carefully observed.

Toxic reactions severe enough to require discontinuation of Tofrānil are uncommon. However, for complete details, please refer to the complete Prescribing Information.

Turn page for brief summary of Prescribing Information.

Tofrānil®, imipramine hydrochloride
Indications: Tofrānil is recommended for the treatment of depressive states of diverse psychopathology.
Contraindications: The concomitant use of this agent and monoamine oxidase inhibiting (M.A.O.I.) compounds is contraindicated. Hyperpyretic crises or severe convulsive seizures may occur. Potentiation of adverse effects can be serious or even fatal. An interval of at least 7 days after M.A.O.I. therapy has been discontinued should be allowed before this drug may be substituted. Initial dosage should be low, increases should be gradual, and the patient's progress should be carefully observed.
Warning: Clinical reports have suggested that there may be a risk of teratogenesis associated with the use of this compound during the first trimester of pregnancy. Unless, in the opinion of the prescribing physician, the potential benefits outweigh the possible risks, it should not be used during the first trimester of pregnancy. Cardiovascular complications, including myocardial infarction and arrhythmias, have occasionally occurred in susceptible individuals. Patients with cardiovascular disease should be given the drug only under careful observation and in low dosage.
Precautions: Since suicide is always a possibility in severely depressed patients and one which may persist until significant remission occurs, such patients should be carefully supervised during early treatment. Some severely depressed patients may also require hospitalization and/or concomitant electroconvulsive therapy. Because of its anticholinergic effect, caution should be observed in prescribing the drug for patients with increased intraocular pressure.
In rare instances, transient cardiac arrhythmias have occurred in hyperthyroid patients and in patients receiving thyroid medication when this compound was added to the regimen. Imipramine may block the pharmacologic activity of guanethidine and other related adrenergic neuron-blocking agents.
The drug is not recommended at the present time in patients under 12 years of age.
Adverse Reactions: Dryness of the mouth, tachycardia, constipation, disturbances of accommodation, sweating, dizziness, weight gain, urinary frequency or retention, nausea and vomiting, peripheral neuritis, mild parkinson-like syndrome, tremors, rare cases of falling in elderly patients, confusional states (with such symptoms as hallucinations and disorientation), activation of psychosis in schizophrenics and agitation (including hypomanic and manic episodes) which may require dosage reduction and/or addition of a tranquilizer or temporary discontinuation of the drug, epileptiform seizures, orthostatic hypotension and substantial blood pressure fall in hypertensive patients, purpura, transient jaundice, bone marrow depression including agranulocytosis, sensitization and skin rash including photosensitization, eosinophilia, and mild withdrawal symptoms on sudden discontinuation after prolonged treatment with high doses. Occasional hormonal effects (impotence, decreased libido, and estrogenic effects) may be observed. Atropine-like effects may be more pronounced (e.g. paralytic ileus) in susceptible patients and in those using anticholinergic agents (including antiparkinsonism drugs).
Outpatient Adult Dosage: Initially, 75 mg. daily, increased, if necessary, to 150 or 200 mg. Maintenance dosage may be lower, 50 to 150 mg. daily, if possible.
Geriatric and Adolescent Dosage: Initially, 30 or 40 mg. daily, which may be increased according to response and tolerance. It is usually unnecessary to exceed 100 mg. daily.
A lag in therapeutic response, lasting from a few days to a few weeks, should be expected. When dosage recommendations are already being followed, increasing the dosage does not normally shorten this latency period and may increase the incidence of adverse reactions.
Availability: Round tablets of 25 and 50 mg.; triangular tablets of 10 mg. for geriatric and adolescent use; and ampuls, each containing 25 mg. in 2 cc. for I.M. administration.

Some Aspects of Lipid Metabolism in Diabetes Mellitus

"Diabetes is a factor inherent in man and related to nutrition. Beyond this one can only speculate."—G. F. Cahill

RAFAEL CARMENA, M.D.
Minneapolis, Minnesota

CLASSICALLY, DIABETES MELLITUS has been considered to be a disturbance of the metabolism of carbohydrates consequent to a relative or absolute lack of insulin. It is well known that important disturbances of the metabolism of lipids—reflected by hyperketonemia and hyperlipidemia—are also present in this condition. As a matter of fact, elevated blood lipids in diabetes were known to Mariet in 1799[1] and Traill in 1823,[2] long before the discovery of the elevated blood sugar concentration by Ambrosiani[3] in 1835.

Hyperglycemia and glycosuria were immediately considered the cardinal signs of the disease and led to dietary treatment based on low carbohydrate. The hyperlipidemia did not cause obvious symptoms and was considered to be secondary to the carbohydrate disturbance.

Cawley in 1788[4] was apparently the first to associate diabetes with the pancreas based on autopsy findings. Attempts by several investigators to reproduce diabetes experimentally failed. In 1879 Langendorf[5] removed the pancreas of chickens and pigeons but the birds did not exhibit glycosuria or hyperglycemia. Mering and Minkowski in 1889[6] proved for the first time that dogs could be made diabetic by pancreatectomy. Minkowski also confirmed the observations of Langendorf in birds and concluded that herbivorous animals, unlike carnivorous ones, do not suffer from diabetes mellitus. The period between 1890 and 1921 saw a tremendous advance in the understanding of the intermediary metabolism of carbohydrates, culminating in the discovery of insulin by Banting and Best[7] in August 1921 and its clinical

*Presented as a Medical Grand Rounds at Hennepin County General Hospital, August 15, 1967.

I wish to express my gratitude to my adviser, Dr. Francisco Grande for allowing me the use of some of his unpublished material.

applications soon thereafter.

By contrast, the intermediary metabolism of lipids experienced a much slower development. Most of our knowledge has actually been acquired in the past two decades, paralleling the development of laboratory techniques. It is striking that until very recently the adipose tissue, some 15 kg. by weight in the average male and 20 in the female, was largely considered to be metabolically inert connective tissue filled with droplets of fat. It was particularly the work of Wertheimer and his associates[8] which proved that the adipose tissue not only has a very important metabolic activity represented by the high turnover of triglycerides, but it is also one of the principal target organs upon which insulin acts. This led the way to many important discoveries, among them the metabolic significance of the nonesterified fatty acids as an important transport form of energy.[9] It also focused attention on matters such as impaired lipid metabolism and atherosclerosis. Since vascular disease causes three fourths of diabetic deaths, it is not surprising that the metabolism of lipids in diabetes mellitus has been intensely investigated in the past few decades.

We shall review briefly some aspects of the alterations of serum lipids in diabetes mellitus with attention to nonesterified-fatty-acid metabolism in mammals and birds and its implications in the diabetic syndrome.

Disturbed Lipid Metabolism

Disturbances in lipid metabolism are an essential part of the deranged metabolism in diabetes mellitus. In the pre-insulin era, milky appearance of the blood due to accumulation of fat in the plasma was frequently seen in patients in diabetic ketosis and acidosis. It was considered to be a bad prognostic sign since it was associated with high mortality. However, its relationship to the metabolism of carbohydrates could not be established until insulin became available. With the use of insulin it was observed that the elevated plasma lipids of patients in diabetic acidosis experienced a sharp descent in very short periods of time. Some of the reported cases[10,11] had initial concentrations as high as 16.0 and 22.9 Gm. of total lipids per 100 ml. of plasma, and these values dropped in a few hours to normal limits after the administration of insulin. The existence of a direct correlation between serum lipid and blood sugar levels was also evidenced by the fact that adequate control of the carbohydrate metabolism resulted in marked reduction of all serum lipid levels.

In Controlled Diabetics

At present, investigators[12] agree that in carefully controlled diabetics there should be no significant elevation of the total blood lipids. However, the nonesterified fatty acids are increased even in well controlled diabetics, particularly if the plasma samples are taken before the morning injection of insulin. When the control of diabetes is not satisfactory, nonesterified fatty acids and triglycerides rise significantly. With very poor control, increases of cholesterol and phospholipids also appear and seem to be related to high incidence of vascular disease.[12]

The type of changes of serum lipids in diabetes seems to depend on the type, maturity or juvenile onset and the duration of the disease. Studies on juvenile insulin-dependent diabetics show a different pattern of lipid alterations than do studies done on maturity onset patients. In a recent publication,

Braunsteiner et al.[13] have investigated the relative body weight and the plasma nonesterified fatty acids, triglycerides, total cholesterol and phospholipids of 87 diabetics with ages ranging from 14 to 87. They were divided into four groups and compared with control groups of subjects of comparable ages with no evidence of metabolic disease. Group I consisted of 12 recently diagnosed diabetics without treatment or ketoacidosis. They found the nonesterified fatty acid and triglyceride fractions to be significantly elevated when compared to the control group. In Group II, 40 well controlled diabetics treated with insulin were studied. The serum cholesterol and phospholipid values were higher than in the control group, and triglycerides and nonesterified fatty acids were significantly elevated. Group III included 30 well controlled diabetics treated with Tolbutamide. The relative body weight was significantly higher than in the control group. The only lipid fraction significantly elevated were the triglycerides. Group IV consisted of five diabetics in ketoacidosis. The nonesterified fatty acids were very significantly increased, with 57% elevation in respect to the control group. The triglycerides also rose. In summary, the most striking differences were found in the concentration of triglycerides and nonesterified fatty acids. Serum triglycerides were elevated in all groups of diabetics. Nonesterified fatty acids were significantly elevated in patients with ketoacidosis and rose also in Groups I and II. An increased concentration of cholesterol or phospholipids was found only in well controlled diabetics treated with insulin. The relative body weight was significantly elevated only in Group III.

In Juvenile Diabetics

There is disagreement in the literature concerning the lipid alterations in juvenile diabetics. Some authors[14,15] have reported no significant changes in serum triglycerides in juvenile diabetics, while others[16,17] have found elevated triglyceride levels, especially in cases with angiopathy. In a recent publication, Hiekkala et al.[18] report on plasma lipids in 149 juvenile insulin-treated diabetics with ages ranging from five to 22 years, whose diabetes had been present for from a few months to 16 years. They have also studied the incidence of angiopathy among the patients as evidenced by the presence of retinopathy and/or nephropathy. Angiopathy was diagnosed in 40 cases, with a duration of diabetes of more than seven years in all of them. Serum cholesterol and phospholipids were found to be significantly elevated in all patients with angiopathy, who were also those with poorer control (high glucose spilling, ketosis and hypoglycemic reactions). In patients with no sign of angiopathy, increase in age or in the duration of the disease did not seem to influence the plasma cholesterol values. Total lipid values were significantly increased in the poorly controlled patients, in cases with duration of diabetes for more than 15 years and in connection with vascular disease. Similar results were also reported by Adlersberg[19] and Larson.[20]

Bahl and Bahl[21] have studied the serum lipids in a group of 75 diabetics in India. Their results showed significant increase in serum cholesterol concentration in 51 cases where vascular disease was diagnosed. Total lipid values were also found to be elevated in the same cases.

In Fasting Samples

Carlson[22] has investigated the concentrations of cholesterol and triglycerides in fasting serum samples and their relationship to the diabetic state.

There was no difference in cholesterol concentration between the patients and normal persons. On the other hand, the triglycerides were significantly increased above the normal level. The studies of Carlson show that the degree of control of carbohydrate metabolism exerts direct influence on the triglycerides. When diabetics are kept under good control (fasting blood sugar below 200 mg % and less than 15 Gm. of sugar in 24 hours' urine) their serum triglyceride values approach those of the control group. In a group of 20 patients with mild ketonuria without acidosis the blood sugar decreased on the average 60 mg % and the triglycerides 100 mg % after insulin was administered. No significant cholesterol changes were seen, probably because of the low turnover rate of cholesterol.

A summary of the present state of our knowledge about the plasma lipids during the course of the diabetic syndrome is presented in the Table, modified from Carlson. The nonesterified fatty acids and triglycerides are elevated from the beginning and can be reduced by treatment but not completely normalized. In the event of ketosis, these two lipid fractions rise markedly, and in the most exaggerated state even cholesterol and phospholipids will increase. When retinopathy or coronary artery disease appears, serum cholesterol is also elevated. In the Kimmelstiel-Wilson syndrome, the fraction that shows the most significant increase is the triglycerides.

Adipose Tissue Metabolism in Mammals and Birds

Adipose tissue is found in all homeotherm animals.[23] It has been said[24] that if animals were to exist without the convenience afforded by the adipose tissue it would be necessary to adjust the rate of absorption of food from the gastrointestinal tract to accommodate different rates of energy expenditure. The mammalian fetus shows a remarkable absence of depot lipids during intrauterine life, because the fetus is continuously fed through the maternal circulation. In post-natal life, animals are intermittent eaters and are con-

Modified from Carlson, L. A.

fronted with the problem of surviving during the fasting periods. Therefor they have to store temporarily much of the chemical energy ingested as food. This is done by lipogenesis and storing of fat in the adipose tissue.

There are several reasons for fat to be the preferred storage material: (a) it takes up less volume and weighs less per calorie of stored chemical energy than either carbohydrate or protein; (b) the body has, perhaps unfortunately, an almost infinite capacity to store fat, in contrast to its very limited capacity to store carbohydrate and protein.

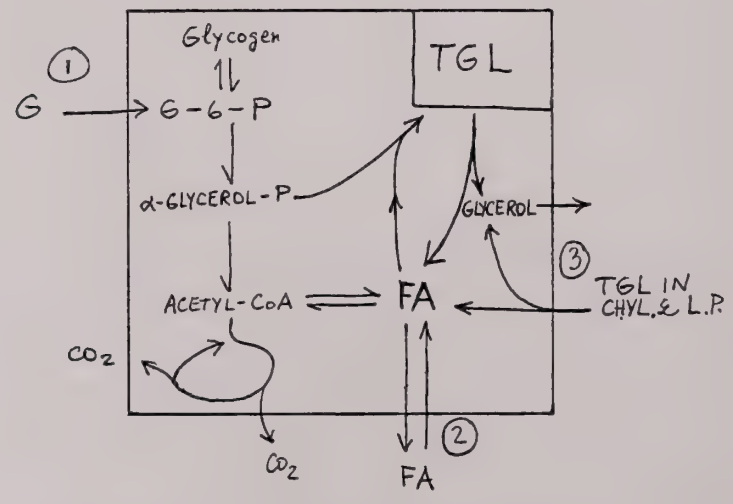
Fat is stored in the adipose tissue as triglycerides, which constitute the major storage form of oxidizable substrate in mammals. There are three main precursors of adipose tissue triglycerides: (a) *nonesterified fatty acids,* demonstrated[25] but not considered to be a major one; (b) *triglycerides,* carried in chylomicrons and low density lipoproteins[25] which are for the most part broken down to glycerol and nonesterified fatty acids and resynthesized again to triglyceride (there is also evidence[26] that they can be taken up by the adipose tissue by pyocytosis); (c) *glucose,* the primary precursor of glycerol for adipose tissue triglycerides. If insulin is available, glucose enters the adipose tissue cells, is phosphorylated to glucose-6-phosphate and follows either the catabolic pathway, leading to triose-phosphate formation, or the anabolic pathway, leading to glycogen. The triose-phosphate pathway leads to the formation of glycerol-phosphate and acetyl-coenzyme A at a later step. It is important that the adipose tissue cells lack glycerol-kinase[27] and are not able to form glycerol-phosphate from free glycerol. The glycerol-phosphate necessary for triglyceride synthesis is derived only from glucose The synthesis of fatty acids requires acetyl-coenzyme A and triphosphopyridine nucleotide, reduced form and both are also derived from the catabolism of glucose.

By using glucose-C^{14}[28] it has been estimated that at a blood glucose of 90 mg % the adipose tissue utilizes 44% of it to form glycerol-phosphate; 42% goes to carbon dioxide, 13% to fatty acids and 1% to glycogen. The mobilization of fat from the adipose tissue occurs exclusively in the form of nonesterified fatty acid.[29] Nonesterified fatty acids are the only output form of adipose tissue triglycerides, in contrast to the multiplicity of modes of input.

Lipolysis and lipogenesis are under the control of neural, metabolic and hormonal factors. We shall review them briefly in normal and diabetic mammals, adding some comments on recent investigations on birds.

Neural Mechanism

The neural mechanism controls instantaneous delivery of fuel by the adipose tissue. It is mediated through the sympathetic system in which the adipose tissue is richly innervated.[30] Several investigators[31,32,33] have reported that the plasma nonesterified fatty acids in animals and man are decreased after the administration of ganglionic or adrenergic blocking agents. Bogdonoff et al.[34] showed that sympathetic discharge associated with emotional stress can elevate plasma nonesterified fatty acids in man.



Metabolic Regulation

The metabolic regulation has also been called "glucose-cum-insulin."[29] The amount of glucose utilization is the main determining factor with respect to the net lipolysis and lipogenesis. When glucose utilization is low (starvation, diabetes) lipolysis exceeds lipogenesis and nonesterified-fatty-acid concentra-

tion in serum rises. Conversely, with excessive insulin and consequent increased glucose utilization, lipogenesis is also increased and nonesterified fatty acids are reincorporated into triglyceride. The explanation of these changes lies in the formation of glycerol-phosphate. Lipolysis continues to take place even at steady state,[35] and in order to maintain the depot fat constant lipogenesis must also be operating. For lipogenesis to occur, glycerol-phosphate has to be available. The only important source of it is the blood glucose. When glucose is not available the glycerol-phosphate requirements are not met and lipogenesis is shut off. The nonesterified fatty acids liberated by lipolysis cannot be re-esterified. They will leave the adipose tissue cell, become bound to albumin and circulate in that manner through the blood stream (Figure 1).

The nonesterified fatty acids are taken up by the tissues and converted to fatty-acetyl-CoA which may then be stored as triglyceride or oxidized to acetyl-CoA, which is converted into citric acid and finally oxidized to CO_2 and water. With the exception of the brain, all tissues are well equipped with enzyme systems for direct oxidation of fatty acids.[36] The skeletal and heart muscles take up most of the circulating nonesterified fatty acids to derive their energy. The liver also takes up nonesterified fatty acids and incorporates them into lipoproteins. When the mobilization of fat reaches high values, the liver's ability to cope with the nonesterified-fatty-acid load is exceeded and deposition of fat in the liver takes place.[29] Under normal circumstances, the half-life time for nonesterified fatty acids in plasma is two to four minutes.[37] If the plasma concentration of nonesterified fatty acids is normally around 600 micro Eq/L and the plasma volume 3 L, the flux of nonesterified fatty acids through the plasma in 24 hours would account for 160 Gm. of fat, about 60% of the daily energy production in man.[36]

The two major fuels for oxidation in mammals are glucose and nonesterified fatty acids. It was only logical to assume an interaction between the metabolism of fatty acids and that of glucose. This was postulated by Randle et

G = Glucose
FA = Fatty Acids
L.P. = Lipoprotein
TGL = Triglycerides
Chyl = Chylomicron

Figure 1

al.[38,39] some years ago and named the "glucose-fatty-acid cycle," the essential features of which are: (a) nonesterified fatty acids release from adipose tissue is inhibited by the uptake of glucose by that tissue; (b) glucose utilization by muscle is decreased by nonesterified fatty acids. The cycle provides a mechanism which, independently of hormonal control, will maintain constant plasma-glucose concentration (Figure 2).

Hormonal Control

The hormonal control is carried out by two different types of action. (a) *Lipogenetic hormones:* The work of Dole[40,41] showed that insulin causes the plasma nonesterified fatty acids to fall sharply. More recent work[42] has proved that insulin lowers the intracellular level of cyclic adenosine monophosphate (AMP) in adipose tissue. The action of insulin can thus be explained as decreasing the release of nonesterified fatty acids from adipose tissue, without affecting the rate of removal from blood. Some recent reports by Böhle[43] and Bergstrom[44] have shown that the prostaglandins can also inhibit lipolysis by blocking the formation of cyclic adenosine monophosphate. (b) *Adipokinetic hormones*: Many hormones have been shown to enhance lipid mobilization, some directly and others by permissive action. Epinephrine and norepinephrine are the most important adipokinetic hormones in mammals. Their action takes place through increased formation of cyclic adenosine monophosphate, which in turn activates the triglyceride lipase.[45] Some authors believe that the action of these hormones is also dependent on activation of the phosphorylases.[35]

Other adipokinetic hormones are somatotropic hormones, adrenocorticotrophic hormones, thyroid-stimulating hormones, thyroxine, adrenal corticoids, follicle-stimulating hormones, glucagon, some pituitary extracts like "frac-

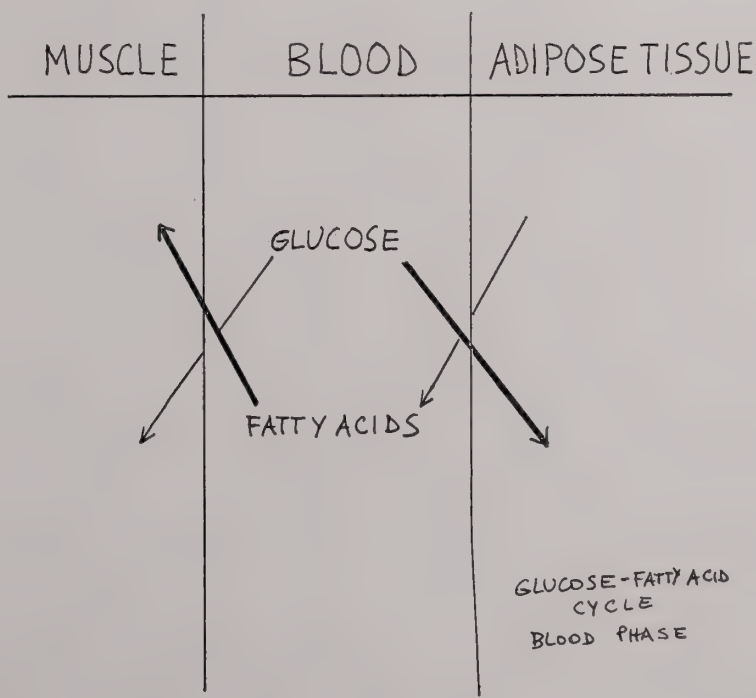


Figure 2

tion H," "peptide I" of Astwood, the "lipid mobilizing factor" of Sefter, the adipokinetic substance found in the urine of fasted normal humans and in that of diabetics.[46] Most of these substances act by favoring the formation of cyclic adenosine monophosphate. Others (adrenal corticoids) have a permissive action and potentiate the effect of epinephrine. However, adrenocortical hormones can, at high concentrations, have a direct effect on nonesterified fatty acid release.[47]

In birds, the recent work done by Grande has proved that epinephrine has no action on fat mobilization from adipose tissue. By constrast, glucagon seems to be the most potent adipokinetic hormone in these animals (duck, goose and rooster.) Moreover, Grande has also shown that in birds insulin does not prevent the mobilization of nonesterified fatty acids induced by glucagon. The administration of insulin at doses which produced a marked decrease of blood sugar did not decrease plasma nonesterified-fatty-acid concentration in birds. The same dose given to mammals caused a marked decrease of plasma nonesterified fatty acids.

Adipose Tissue Metabolism in Diabetes Mellitus

The alterations present in the adipose tissue of diabetic patients can be summarized as: (1) decreased glucose utilization, (2) increased release of nonesterified fatty acids to the blood and (3) decreased uptake of trigylcerides from the blood. These changes represent the increased lipid mobilization that occurs in clinical[48] and experimental diabetes.[41] It has been suggested[38] that part of the disturbances of carbohydrate metabolism characteristic of the diabetic state are not a direct consequence of insulin lack but a result of the increased mobilization and utilization of nonesterified fatty acids. As experiments in animals have shown,[53] complete removal of the pancreas is immediately followed by rise in plasma nonesterified fatty acids. This alteration precedes the elevation of the blood sugar.

In their "glucose-fatty acid cycle," Randle et al.[38] postulated that the increase in plasma nonesterified-fatty-acid concentration causes increased nonesterified-fatty-acid utilization by the muscle. This leads to decreased glucose utilization and in turn results in decreased sensitivity to insulin. This theory could provide a reasonable explanation for many unexplained features of human diabetes. According to Randle (Figure 3), the sequence of events in early diabetes might be as follows: (1) The breakdown of glycerides in the adipose tissue and muscle is increased with fasting in spite of a normal or raised plasma level of insulin. (2) After food ingestion, insulin in plasma rises higher and so does blood glucose, resulting in inhibition of the lipolysis in the adipose tissue but not in the muscle, where insulin does not affect glyceride breakdown. (3) Since plasma glucose and insulin are high, uptake of glucose by the adipose tissue is also very high, resulting in increased lipogenesis and deposition of large amounts of triglyceride in the adipose tissue. (4) Lipolysis in the adipose tissue is shut off. Nonesterified-fatty-acid levels in plasma will decrease and this will allow the entrance of blood glucose in the muscle. The immediate result is a fall in blood glucose levels, and in some cases hypoglycemic values may be reached, as in some diabetics, two to three hours after meals. (5) The fall in blood glucose causes the insulin level to decline, and lipolysis in the adipose tissue begins. Nonesterified-fatty-acid concentration in plasma will rise again and the cycle will proceed. The evolution from prediabetes to diabetes will appear when the pancreas is un-

able to respond to the increased insulin requirements.[52] The elevation of the fasting blood sugar level will be the immediate consequence.

Other investigators have supported Randle's theory with experimental evidence in vitro.[49] The adipose tissue from diabetic patients and from animals with experimental diabetes has been shown to release nonesterified fatty acid and glycerol at a higher rate than the corresponding normal tissue.

There are also studies done in vivo supporting that theory. Delorme[50] studied in the dog the effect of insulin injections on blood glucose at two different levels of plasma nonesterified fatty acids. When plasma nonesterified fatty acids were raised by a previous infusion of norepinephrine, the fall in blood glucose after insulin injection was significantly less than when nonesterified-fatty-acid concentration in plasma was kept normal. However, the results are questionable because of the use of norepinephrine.

Schalch and Kipnis[51] have studied in man the carbohydrate tolerance after an acute and sustained elevation of nonesterified fatty acids. In order to avoid endocrine or nutritional influences, nonesterified-fatty-acid levels in plasma were raised by the ingestion of 60 Gm. of emulsified corn oil followed in three hours by 50 mg. of heparin intravenously. The carbohydrate tolerance was measured with intravenous injection over four minutes of 25 Gm. of glucose. They studied 12 normal subjects and five patients with diabetes mellitus controlled on diet alone. Their results indicate that in man an elevation of plasma nonesterified-fatty-acid concentration may be associated with an impaired glucose tolerance and decreased target organ sensitivity to insulin. The degree of impairment in carbohydrate tolerance was found to be in direct correlation with the elevation of the plasma nonesterified-fatty-acid level.

Felber et al.[52] have investigated also the correlation between plasma nonesterified-fatty-acid values and glucose tolerance. They measured the carbohydrate tolerance in a group of normal subjects by ingestion of 100 Gm.

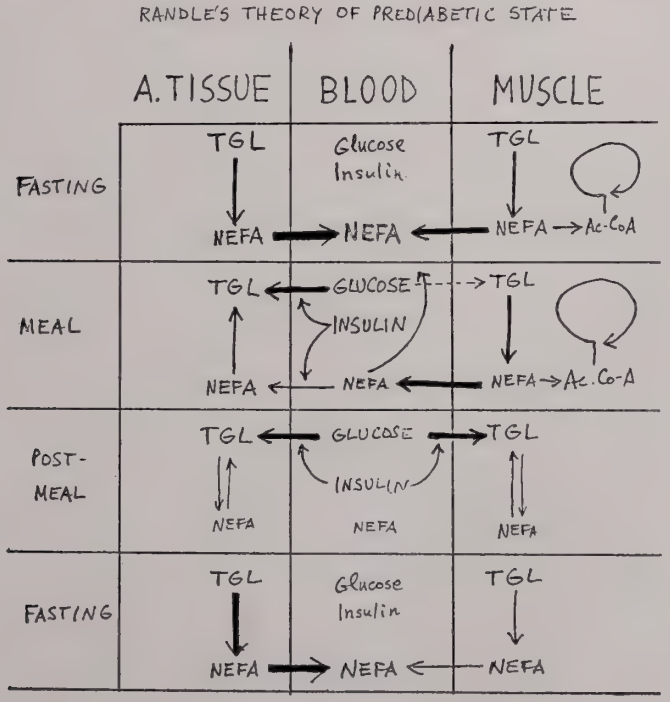

Figure 3

of glucose. The plasma nonesterified fatty acids were raised by ingestion of an emulsion of neutral fat and the glucose tolerance test was repeated. All subjects showed impaired glucose tolerance. These authors also studied the glucose tolerance of 13 obese subjects as compared with a group of normal people. The obese had elevated plasma nonesterified-fatty-acid value at fasting and showed a significant impairment of the glucose tolerance.

The effect of a low calorie diet on plasma nonesterified-fatty-acid level and glucose tolerance has been studied by Stowers et al.[54] They maintained a group of 15 severely obese subjects on a 2,500-calorie diet and measured their carbohydrate tolerance with intravenous and oral administration of glucose. The subjects were then switched to a 600-calorie diet, which caused a significant elevation of their plasma nonesterified fatty acid. The repetition of the carbohydrate tolerance test showed a significant impairment of the glucose tolerance, which was directly correlated to the elevation of nonesterified fatty acids.

Summary

In summary, elevation of plasma nonesterified-fatty-acid levels, whether present spontaneously or artificially provoked, is associated with a lower tolerance to carbohydrates. There are indications that this could be the first metabolic derangement leading to diabetes mellitus. The failure of pancreatectomy to produce diabetes mellitus in some avian species could be due to the fact that insulin does not prevent the mobilization of nonesterified fatty acids in these animals. According to Grande, pancreatectomized birds do not develop diabetes mellitus because their nonesterified-fatty-acid levels do not rise after pancreatectomy, as they do in mammals. If birds can be made diabetic by artificial elevation of the nonesterified-fatty-acid concentration, the hypothesis of Grande will receive full support. The theory that elevation of nonesterified fatty acids is an important first step in the development of the diabetic disturbance will be also further supported. This would considerably advance our understanding of the complex mechanisms responsible for initiating diabetes mellitus in man. Diabetes mellitus could be initially an essential metabolic disturbance becoming secondarily an endocrine disturbance.[52]

In the clinical field, impairment of glucose tolerance in the presence of high plasma nonesterified-fatty-acid values could become a very practical tool in the detection of pre-diabetics. Subjects responding to glucose tolerance tests with values in the border limits of normality will show marked impairment of their carbohydrate tolerance if their plasma nonesterified fatty acids are elevated prior to the test. We believe the data we have reviewed fully support the theory that alterations in lipid metabolism are a very important part of the complex metabolic alterations present in diabetes mellitus. The idea that a diabetic is "well controlled" because sugar-spilling, fasting blood sugar and ketonuria are low or absent should be modified. Plasma levels of nonesterified fatty acids, triglycerides, cholesterol and phospholipids should also be included among the routine laboratory tests for the detection and control of diabetes mellitus, and their values should be kept as close to normal as possible. This will probably result in a lower incidence of vascular complications in diabetics.

Case Report

A 54-year-old white female was admitted for the first time to Hennepin County General

Hospital on August 28, 1964, because of acute cellulitis of the left foot. The patient had been in good health until four days after admission, when she injured her foot on a piece of glass.

P. H. In May, 1964, she was treated at the Emergency Room for an indolent infected laceration of the right leg. Since that time she noticed increased frequency of urination, nocturia and increase in appetite.

F. H. No diabetes, tuberculosis or cancer. Mother died age 24 of acute appendicitis. Father died age 74 of heart attack. One sister had hypoglycemia.

S. H. Married, no children, works as cleaning lady in office building.

Positive Findings

Obese white female with an acutely swollen and tender left foot. Blood pressure 140/80; pulse 112, regular; temperature 101°.

Eyes: Right fundus showed microaneurysms and scattered exudate.

Extremities: Left foot swollen, erythematous and warm.

Laboratory Data

Hemoglobin 11.7; white blood count 19,200; fasting blood sugar 261 and 400 the following day; urinalysis: 3+ glucose, 3+ acetone and 1+ albumin.

Hospital Course

The left foot was treated surgically, followed by a course of penicillin. The patient was diagnosed as having diabetes mellitus and was started on regular insulin 30 units increasing up to 55 units on the third hospital day. She was switched to 40 units of insulin and later to Tolbutamide 500 mg. q. 6 h. She was discharged on September 22, 1964, on Tolbutamide 500 mg. b.i.d. and 1,200-calorie diet.

Follow-Up

The patient has been admitted to Hennepin County General Hospital on two subsequent occasions, the last on May, 1967. At that time she was found to have bitaleral retinopathy with exudates and microaneurysm scattered over both fundi. Fasting blood sugar ranged from 156 to 296; serum cholesterol 350. An electrocardiogram was read as borderline, with some ST depression in V_6. The patient was switched to Tolinase 250 mg. q. i. d. and 1,800-calorie diet. She is presently being followed at the Diabetic Clinic in the Out-Patient Department. Her latest laboratory work, July 28, 1967, showed fasting blood sugar 188, serum cholesterol 350, serum triglyceride 214 mg. %, and total blood lipids 923 mg. %.

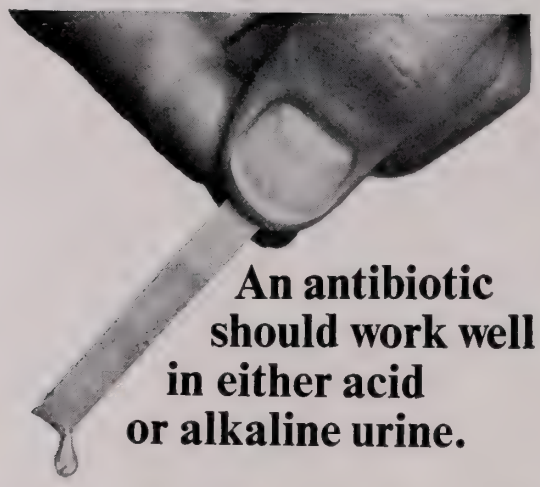
To the Young Practitioner

Your patient has no more right to all the truth you know than he has to all the medicine in your saddle-bags, if you carry that kind of cartridge-box for the ammunition that slays disease. . . . Some shrewd old doctors have a few phrases always on hand for patients that will insist on knowing the pathology of their complaints without the slightest capacity of understanding the scientific explanation. I have known the term "spinal irritation" serve well on such occasions, but I think nothing on the whole has covered so much ground, and meant so little, and given such profound satisfaction to all parties, as the magnificent phrase "congestion of the portal system."*



*Oliver Wendell Holmes

They May Have A Point

One of the factors encouraging quackery is the doctor's neglect of the complexity of the patient's first complaint.—J. A. Weijel

---

Temperance and labor are the two true physicians of man.—Jean Jacques Rousseau

An antibiotic should work well in either acid or alkaline urine.

It isn't always necessary to adjust urinary pH in treating G.U. infections.

Not when the causative organism is a strain sensitive to DECLOMYCIN® Demethylchlortetracycline, as is often the case.

DECLOMYCIN remains stable and active in either acid or alkaline urine. So there's no need to acidify the urine to keep the antibiotic at work.

Why match the urine to the antibiotic...when you can match the antibiotic to the urine...by prescribing DECLOMYCIN. A b.i.d. dosage makes therapy convenient for your patient.

Effectiveness: DECLOMYCIN Demethylchlortetracycline should be equally or more effective therapeutically than other tetracyclines in infections caused by organisms sensitive to the tetracyclines.

Contraindication: History of hypersensitivity to demethylchlortetracycline.

Warning: In renal impairment, usual doses may lead to excessive accumulation and liver toxicity. Under such conditions, lower than usual doses are indicated, and, if therapy is prolonged, serum level determinations may be advisable. A photodynamic reaction to natural or artificial sunlight has been observed. Small amounts of drug and short exposure may produce an exaggerated sunburn reaction which may range from erythema to severe skin manifestations. In a smaller proportion, photoallergic reactions have been reported. Patients should avoid direct exposure to sunlight and discontinue drug at the first evidence of skin discomfort. Necessary subsequent courses of treatment with tetracyclines should be carefully observed.

Precautions: Overgrowth of nonsusceptible organisms may occur. Constant observation is essential. If new infections appear, appropriate measures should be taken. In infants, increased intracranial pressure with bulging fontanels has been observed. All signs and symptoms have disappeared rapidly upon cessation of treatment.

Side Effects: Gastrointestinal system – anorexia, nausea, vomiting, diarrhea, stomatitis, glossitis, enterocolitis, pruritus ani. Skin – maculopapular and erythematous rashes; a rare case of exfoliative dermatitis has been reported. Photosensitivity; onycholysis and discoloration of the nails (rare). Kidney – rise in BUN, apparently dose-related. Transient increase in urinary output, sometimes accompanied by thirst (rare). Hypersensitivity reactions–urticaria, angioneurotic edema, anaphylaxis. Teeth – dental staining (yellow-brown) in children of mothers given this drug during the latter half of pregnancy, and in children given the drug during the neonatal period, infancy and early childhood. Enamel hypoplasia has been seen in a few children. If adverse reaction or idiosyncrasy occurs, discontinue medication and institute appropriate therapy. Demethylchlortetracycline may form a stable calcium complex in any bone-forming tissue with no serious harmful effects reported thus far in humans.

Average Adult Daily Dosage: 150 mg q.i.d. or 300 mg b.i.d. Should be given 1 hour before or 2 hours after meals, since absorption is impaired by the concomitant administration of high calcium content drugs, foods and some dairy products. Treatment of streptococcal infections should continue for 10 days, even though symptoms have subsided.

Capsules: 150 mg; Tablets: film coated – 300 mg, 150 mg and 75 mg of demethylchlortetracycline HCl.

Abstracts, Briefs and Commentaries

METASTASES FROM SQUAMOUS CELL CARCINOMAS OF THE SKIN

The authors with the assistance of the California Tumor Registry studied 6,900 squamous cell skin cancers for metastatic potential. Out of the total number of cases studied there were 142 cases with metastases to the regional lymph nodes or distant sites. This represented 2% of the total number of cases studied. In their study the authors did not include squamous cell cancer of the mucous membranes. Out of the total number of patients studied, the median age was 72 years with women having a median of 77 years, while the median age for men was 69. In their series 67% of the primary lesions occurred on the exposed areas of the body. The authors point out the importance of malignant degeneration ensuing from actinic change in the skin and the metastatic potential of such lesions. Of the 142 squamous cell skin cancers which were reported to have metastasized (2% of the 6,900 cases studied), metastases reached the lung in approximately 4.9%; and in 6% spread was considered to be generalized. Of the group of 117 patients who were followed for at least five years after diagnosis, 57% died of their skin cancer.

Comment: The authors point out that some studies in recent years have led to a complacency concerning the metastatic potential of squamous cell carcinoma of the skin. This report shows that squamous cell carcinomas of the skin which arise from actinic change as well as those which arise from chronic ulcers and radiodermatitis may and do metastasize. Even though squamous cell carcinomas of the skin are considered to be of low malignant potential, they are nevertheless capable of widespread metastatic disease. Therefore they should be diagnosed early and treated aggressively, with an adequate follow-up of at least five to 10 years.

THE PILL AND PSEUDOCANCER OF CERVIX AND BREAST

In the January 29 issue of JAMA, Candy and Akell, of the pathology department at the University of Michigan, reported 12 patients with adenomatous hyperplasia of the cervix. Most cervixes had malignant looking verrucose or polypoid masses at the squamous columnar junction. Eight patients had taken Enovid, three Ortho-Novum, and one Provera. In two thirds of patients, clinicians considered the lesions malignant. Further, pathologists interpreted three biopsies as adenocarcinoma, and patients were sent to University of Michigan for radiation. These pathologists recognized all 12 cervical growths as adenomatous and cribiform hyperplasia of gland and reserve cells. No lesions recurred after they were excised or cauterized.

About one week after the JAMA article, a report appeared in the January issue of the *American Journal of Clinical Pathology* on Enovid-induced breast masses. Its authors, three pathologists at the University of Washington, report four patients, aged 35, 31, 20, and 21, who had "florid" fibroadenomas. These patients had taken Enovid from two months to two years, and they presented with firm breast masses. In each case, surgeons easily enucleated the nodules, but the masses' hardness concerned them. The pathologists, in their turn, were disturbed by the "severe epithelial proliferation." Finally the presence of secretory droplets in cells, lack of cellular atypism, and the existence of capsule convinced them the lesions were benign. When the patients were followed for 10 to 44 months, no lesions recurred. The authors did, however, see three more breast biopsies with Enovid-induced fibroadenomas.

MALIGNANT TUMORS IN SMALLPOX VACCINATION SCARS

Malignant degeneration occurring in a prior vaccination scar is a delayed complication to this procedure which has recently received increased attention. In the present study the authors report on 24 patients with proven malignant tumors originating in smallpox vaccination scars. The tumors included malignant melanoma, squamous cell carcinoma and basal cell epithelioma. The period of latency between the vaccination and occurrence of the tumor was in most cases many years. The authors, because of this prolonged latent period, concluded that a viral etiology for the occurrence of tumors in vaccination scars was only a remote possibility. A more plausible suggestion was the tendency of older scars to undergo malignant degeneration. Another factor to consider was the individual susceptibility of each of the patients studied to develop cutaneous cancer (six of 13 patients who developed basal cell carcinomas in their vaccination scars had multiple tumors). It is concluded that further clinical, epidemiological, and laboratory studies should be made to determine if the vaccinia virus has any role in the production of malignant tumors in man.

GALLBLADDER DISEASE IN DIABETICS

Diabetics do not withstand the complications of gallbladder disease as well as other people.

Between 1947 and 1960 a total of 145 diabetics with cholelithiasis and cholecystitis were admitted to Massachusetts General Hospital. Mundth compares results in these cases with those in 150 nondiabetics operated on for acute cholecystitis.

Of the 145 diabetics 43 were treated without operation. Of the 102 patients treated surgically, 99 had a cholecystectomy with or without exploration of the common duct, and three had a cholecystostomy.

The operative mortality was 22 percent and the incidence of postoperative complications was 51 percent in the surgically treated diabetics, as compared with 0.7 percent and 11 percent respectively in the nondiabetics. Diabetics have a special liability to gallstones; incidence is 25 percent in diabetics against 8 percent in nondiabetics.

Patients with mild diabetes tolerated elective biliary tract surgery very well. The operative mortality and morbidity were not significantly different from those in nondiabetics.

It is recommended that early elective cholecystectomy should be carried out in all diabetics known to have cholelithiasis, unless a specific contraindication is present.

PHOTOSENSITIVITY STUDIES WITH DEMETHYLCHLORTETRACYCLINE AND DOXYCYCLINE

In this study 30 health volunteers were used as subjects. Ten of the volunteers were given demethylchlortetracycline (600 mg a day), 10 were given doxycycline (200 mg a day) and 10 were given a placebo. The volunteers were on their respective medication for one week, and then exposed to five hours of sunshine off the southeast coast of Florida. Following this exposure the subjects were examined by three physicians who were unaware which drug each person had been taking. Results were as follows: nine out of 10 subjects taking demethylchlortetracycline showed what was interpreted as a photosensitive type of eruption; two of the ten receiving doxycycline had similar reactions. One person on the placebo showed an exaggerated response.

Comment: The authors point out that sun-induced reactions to demethylchlortetracycline are believed to be phototoxic in nature and that there is a high degree of susceptibility to this reaction among most people who receive the drug if adequate sun exposure follows. They also concluded that on the basis of the information in the present study, the use of doxycycline would be associated with less photosensitivity than demethylchlortetracycline.

PERSISTENT CARCINOMA OF CERVIX

A pathological review of 83 pelvic exenteration specimens for persistent or extensive carcinoma of the cervix showed the carcinoma to be more extensive than clinically apparent. The urinary bladder was invaded in 61% of the cases and the rectosigmoid in 44%. A poor prognosis was associated with large bowel invasion, but 27.7% of the patients survived for five years. Sur-

vival was mostly dependent on finding lymph node metastases. The most characteristic alteration of irradiation was the finding of subintimal foam cell plaques in small arteries, especially near the sites of necrosis.

PERITONEAL DIALYSIS IN SALICYLATE POISONING

Four cases of salicylate intoxication were treated by continuous peritoneal dialysis. Observations showing the extensive depletion of available body base, especially potassium, are reported. The clinical states appear to parallel these, rather than the serum salicylate levels. During dialysis the major repair process is correction of electrolyte depletions, which permits the effective renal excretion of salicylate. The various therapeutic measures available for treating salicylate intoxication are reviewed. Peritoneal dialysis is the simplest and most freely available of these. It is suggested on the basis of this experience that prevention of salicylate intoxication now depends largely on accuracy of information in manufacturers' advertising.

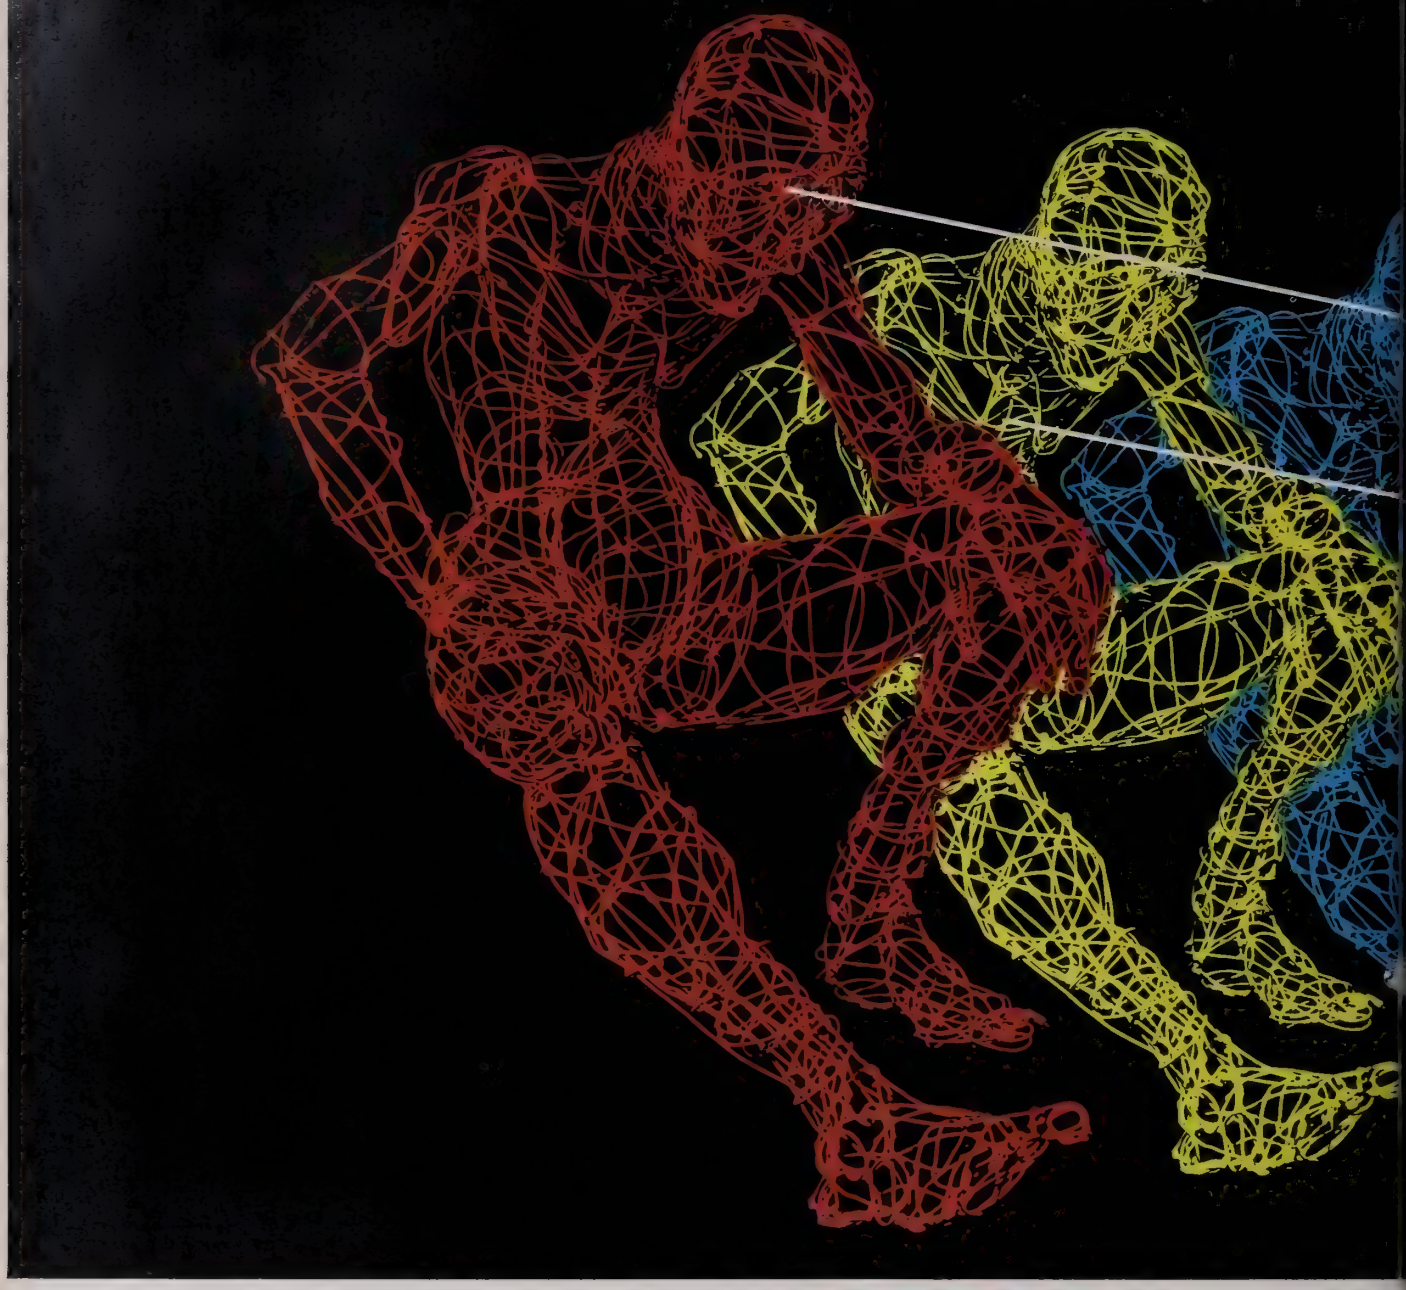
He's had enough excitement for one day.

For the patient who has been through an accident, the worry and anxiety following the experience may actually heighten the perception of pain. This is why there's a classic 1/4 grain *sedative* dose of phenobarbital in Phenaphen with Codeine—*to take the nervous "edge" off,* so the rest of the formula can control the pain more effectively.

Phenaphen® with Codeine

Phenaphen® with Codeine No. 2, No. 3, or No. 4 contains: *Phenobarbital* (1/4 gr.), 16.2 mg. (Warning: may be habit forming); Aspirin (2 1/2 gr.), 162.0 mg.; Phenacetin (3 gr.), 194.0 mg.; Hyoscyamine sulfate, 0.031 mg.; Codeine Phosphate, 1/4 gr. (No. 2), 1/2 gr. (No. 3), or 1 gr. (No. 4). (Warning: may be habit forming).



THE COMPOUND ANALGESIC THAT CALMS INSTEAD OF CAFFEINATES

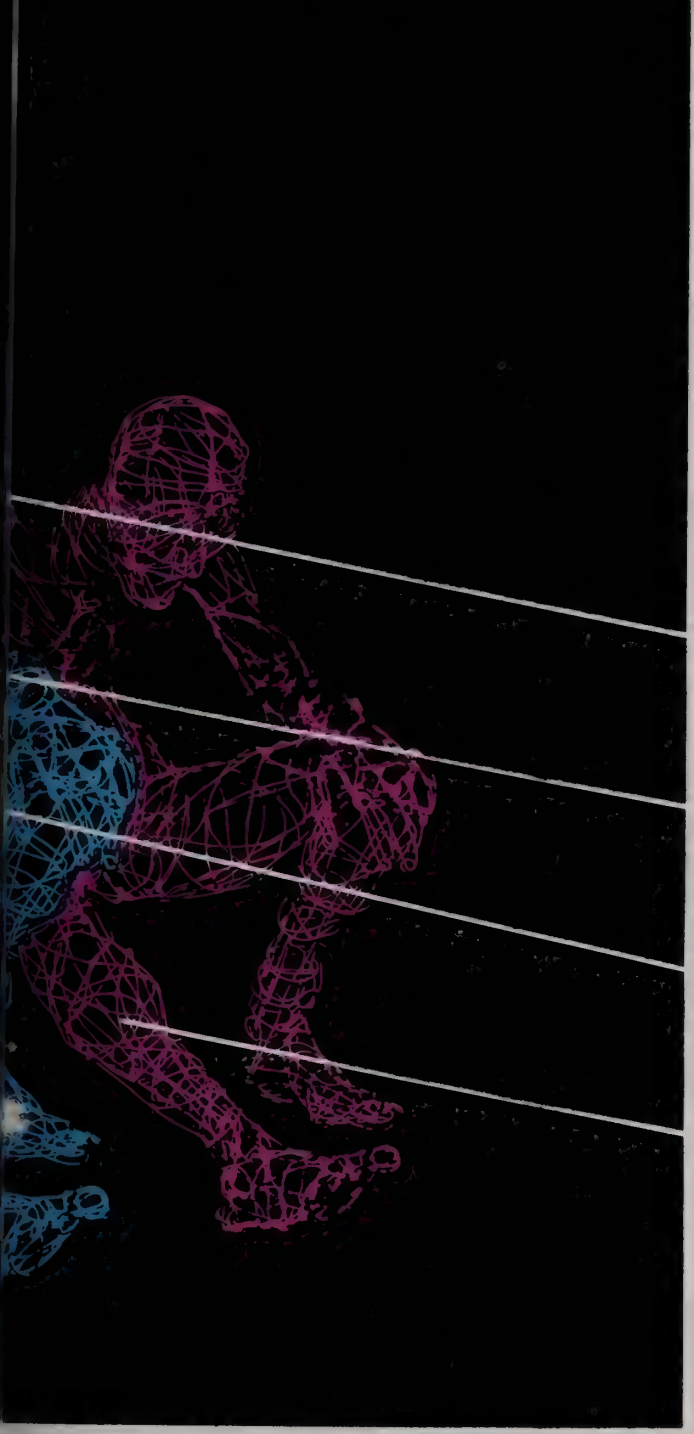
Indications: Phenaphen with Codeine provides relief in severer grades of pain, on low codeine dosage, with minimal possibility of side effects. Its use frequently makes unnecessary the use of addicting narcotics. **Contraindications:** Hypersensitivity to any of the components. **Precautions:** As with all phenacetin-containing products excessive or prolonged use should be avoided. **Side effects:** Side effects are uncommon, although nausea, constipation and drowsiness may occur. **Dosage:** 1 or 2 capsules at 2 to 4 hour intervals, or as directed by physician. For further details see product literature.

A. H. ROBINS COMPANY
RICHMOND, VA. 23220 A·H·ROBINS

a comprehensive hematinic

Description: Each Pulvule® contains—

Special Liver-Stomach Concentrate, Lilly (containing Intrinsic Factor)	150	mg.
Cobalamin Concentrate, N.F., equivalent to Cobalamin (The total vitamin B_{12} activity in the Special Liver-Stomach Concentrate, Lilly, and the Cobalamin Concentrate, N.F., is 15 micrograms.)	7.5	mcg.
Iron, Elemental (as Ferrous Fumarate)	110	mg.
Ascorbic Acid (Vitamin C)	75	mg.
Folic Acid	1	mg.



Indications: Trinsicon® (hematinic concentrate with intrinsic factor, Lilly) is a multifactor preparation effective in the treatment of anemias that respond to oral hematinics, including pernicious anemia and other megaloblastic anemias and also iron-deficiency anemia.

Contraindications: Hemochromatosis and hemosiderosis.

Precautions: Anemia is a manifestation that requires appropria investigation to determine its cause or causes.

In pernicious anemia, the use of folic acid without adequa vitamin B_{12} therapy may result in hematologic remission but ne rological progression. Adequate doses of vitamin B_{12} (parenter or oral with potent intrinsic factor as in Trinsicon® [hematir concentrate with intrinsic factor, Lilly]) usually prevent, halt, improve the neurological changes.

As with all preparations containing intrinsic factor, resistan may develop in some cases of pernicious anemia to the potent tion of absorption of physiological doses of vitamin B_{12}. If resi ance occurs, parenteral therapy, or oral therapy with so-call massive doses of vitamin B_{12}, may be necessary. No single re men fits all cases, and the status of the patient observed follow-up is the final criterion for adequacy of therapy. Perioc

You can treat combined deficiencies with

Trinsicon®

—the multifactor hematinic

Vitamin B_{12} plus intrinsic factor (15 mcg. B_{12} activity)—helps provide adequate levels of this important vitamin.

Folic acid (1 mg.)—treats nutritional macrocytic anemias and/or malabsorption syndromes.

Ascorbic acid (75 mg.)—augments the conversion of folic acid to its active form and helps iron absorption.

Iron (110 mg.)—treats hypochromic anemia.

clinical and laboratory studies are considered essential and are recommended.

Adverse Reactions: In rare instances, iron in therapeutic doses produces gastro-intestinal reactions, such as diarrhea or constipation. Reducing the dose and administering it with meals will minimize these effects.

In extremely rare instances, skin rash suggesting allergy has followed oral administration of liver-stomach material. Instances of apparent allergic sensitization have also been reported after oral administration of folic acid.

Dosage: One Pulvule twice a day. (Two Pulvules daily produce a standard response in the average uncomplicated case of pernicious anemia.)

How Supplied: Pulvules Trinsicon® (hematinic concentrate with intrinsic factor, Lilly), in bottles of 60 and 500. [032566]

Additional information available to physicians upon request.

Eli Lilly and Company, Indianapolis, Indiana 46206.

In peptic ulcer: the antacid puzzle

solved by Mylanta®

aluminum and magnesium hydroxides *plus* simethicone

"will it ease the pain?"

Mylanta helps relieve ulcer pain with the two most widely prescribed antacids: aluminum and magnesium hydroxides.

will it help "my gassy stomach"?

Mylanta *also* contains simethicone: for concomitant relief of G.I. gas distress.

"will this one taste O.K.?"

The *prolonged* acceptance of Mylanta was recently confirmed in 87.5% of 104 patients—after a total of 20,459 documented days of therapy.* *Danhof, I. E.: Report on file.

Composition: Each Mylanta chewable tablet or teaspoonful (5 ml.) contains: magnesium hydroxide, 200 mg.; aluminum hydroxide, dried gel, 200 mg.; simethicone, 20 mg. *Dosage:* One or two tablets (well chewed or allowed to dissolve in the mouth) or one or two teaspoonfuls to be taken between meals and at bedtime.

The Physician's Workshop

In Spring a Young Man's Fancy Turns to - -

IN THESE EXCITING times of great surgical advances, medical men cannot help but be stimulated to strive harder to solve tough medical problems.

The following account of a lay attempt to transplant a bean into a human being may be of interest: immediate voluntary rejection by the host created a challenging problem for his medical attendant.

A mini-corkscrew and a mini-orifice (the external auditory meatus) were featured in this spring-time happening. The 17-year-old patient was planting beans known to some as black-eyed peas. This bean is kidney-shaped and has a thin, very friable skin. The interior is composed of dry, hard starch stored to provide the sprouting plant with food. The bean measures 10 mm in length, 20 mm in girth and about 7 mm in diameter in the midsection.

For some reason the patient decided to plant one experimentally in his left ear and it progressed down the auditory canal to be stopped by the tympanum. The consequences of his action gradually dawned upon him as attempts to remove this seemingly innocuous object failed. Naturally he sought medical help, and, of course, it was on a weekend.

He was fortunate in finding a doctor sympathetic and willing to wrestle with his problem. The doctor found the bean tightly wedged, a perfect fit, deep in the osseous portion of the auditory canal so that removal by retrograde water-jet was impossible. The end of the bean could just be discerned in the canal and any pressure applied to the bean was transmitted to the tympanum and evoked immediate distress. An attempt was made to grasp the bean by means of mosquito hemostats in the hope that the skin would be strong enough to permit the whole bean to be withdrawn intact. Needless to say, the skin broke at once. Further attempts at grasping the bean resulted in crumbling of the visible portion until it became obvious that removal was going to require the skills of a specialist. It was feared that possible delay with consequent swelling of the bean by absorption of moisture would be detrimental—quite apart from the possibility of the bean sprouting out of his ear.

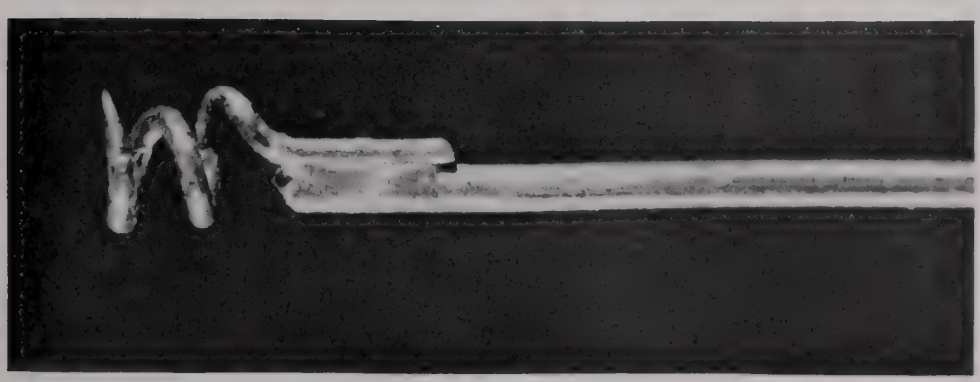

Figure 1

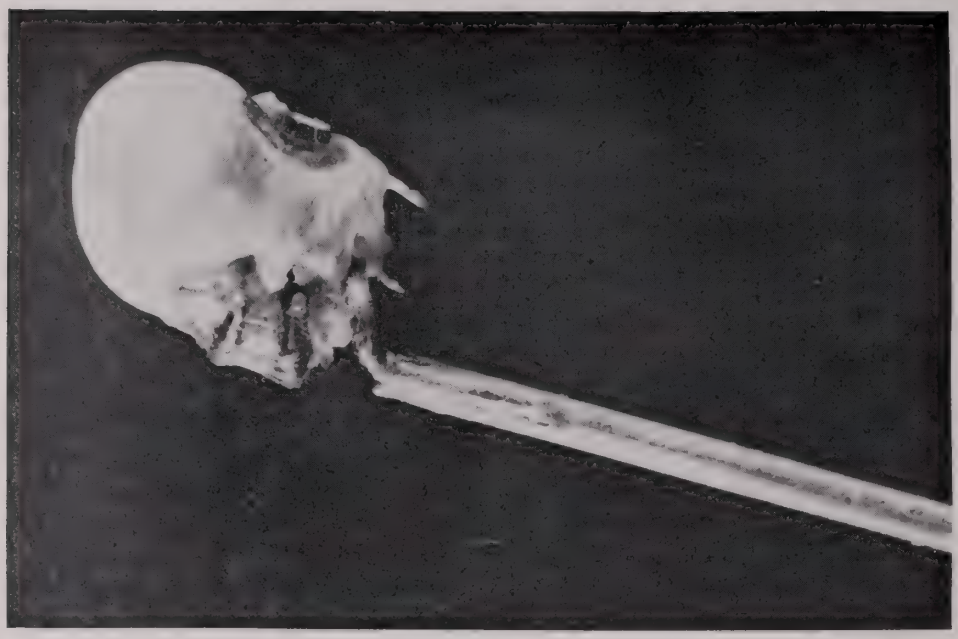

Figure 2

The young patient was a man of moderate means and limited patience; so the problem required the utmost ingenuity to solve quickly and economically. Hooking was tried by bending a sharp pin point, but it was found impossible to slide the hook down between the bean and the lining membrane of the canal because of the exquisite sensitivity of the membrane.

A mini-corkscrew was the answer to the problem of removal. A sharp pointed steel sewing pin was coiled around a small nail held in a vise, taking care not to damage the point. The head of the pin was cut off and the shaft was soft soldered to a piece of stiff brass wire. The finished instrument is shown in Figure 1. The corkscrew coil measured 3 mm in outside diameter. The point was carefully bent so as to lie within the major diameter of the coils of the corkscrew in order to avoid trauma to the lining membrane of the auditory canal as the instrument was rotated.

The finished instrument was carefully screwed into the bean and it was surprising how much force was necessary to extract the bean shown attached to the corkscrew in Figure 2. Happily the patient was able to return to his bucolic pursuits at once and has had no sequelae.

The author will be most happy to donate this instrument to or to make one for any of his colleagues who may anticipate such a problem in their practice.

Book Reviews

A book is a mirror: if an ass peers into it, you can't expect an apostle to look out.—Georg Lichtenberg

TEXTBOOK OF ANATOMY AND PHYSIOLOGY IN RADIOLOGIC TECHNOLOGY—By Charles A. Jacobi. 421 pages. 187 illustrations. Published by C. V. Mosby, 1968. Price $12.00.

This 200-page monograph fulfills the necessity of providing a good practical working knowledge of anatomy and related physiology for students of radiologic technology. The material presented in this text has a readable style and a simple organizational structure. Each chapter is annotated with an adequate bibliography and reference source. The illustrations are plentiful and are excellently reproduced.

There are 12 chapters in this text. Chapters 1, 2, and 3 introduce the reader to anatomy and physiology, body structures and functions, and an embryologic survey. The remaining chapters expose the nine commonly recognized body systems.

Perhaps the greatest compliment that can be given this text is the space in which the material is presented. Mr. Jacobi does not overstress any particular subject, but covers quite adequately all the important needed information for the radiologic technology student. I highly recommend this book for all schools of Radiologic Technology.

THE CARE OF THE GERIATRIC PATIENT—E. V. Cowdry, 430 pp., C. V. Mosby, St. Louis, 1968, $15.75

This is the third edition of Cowdry's editorship of a book on this subject. Cowdry compares geriatrics to pediatrics and considers that the science of the aged is as deserving of special attention by the profession as infant care. Just as a five-year-old is not just a small man, so a seventy-year-old is not just a shriveled adult. Chapters on nursing care, nursing homes, home care, living arrangements, and rehabilitation point out how many ancillary needs of the aged must be considered along with total medical care. There is also a chapter on spiritual aspects written by a Catholic, a Protestant, and a Jew concerning the needs of the members of these faiths. The value of clerical help in a hospital would be enhanced if any of the three would address himself also to the spiritual problems of the patients uncommitted to these religions, or perhaps to any.

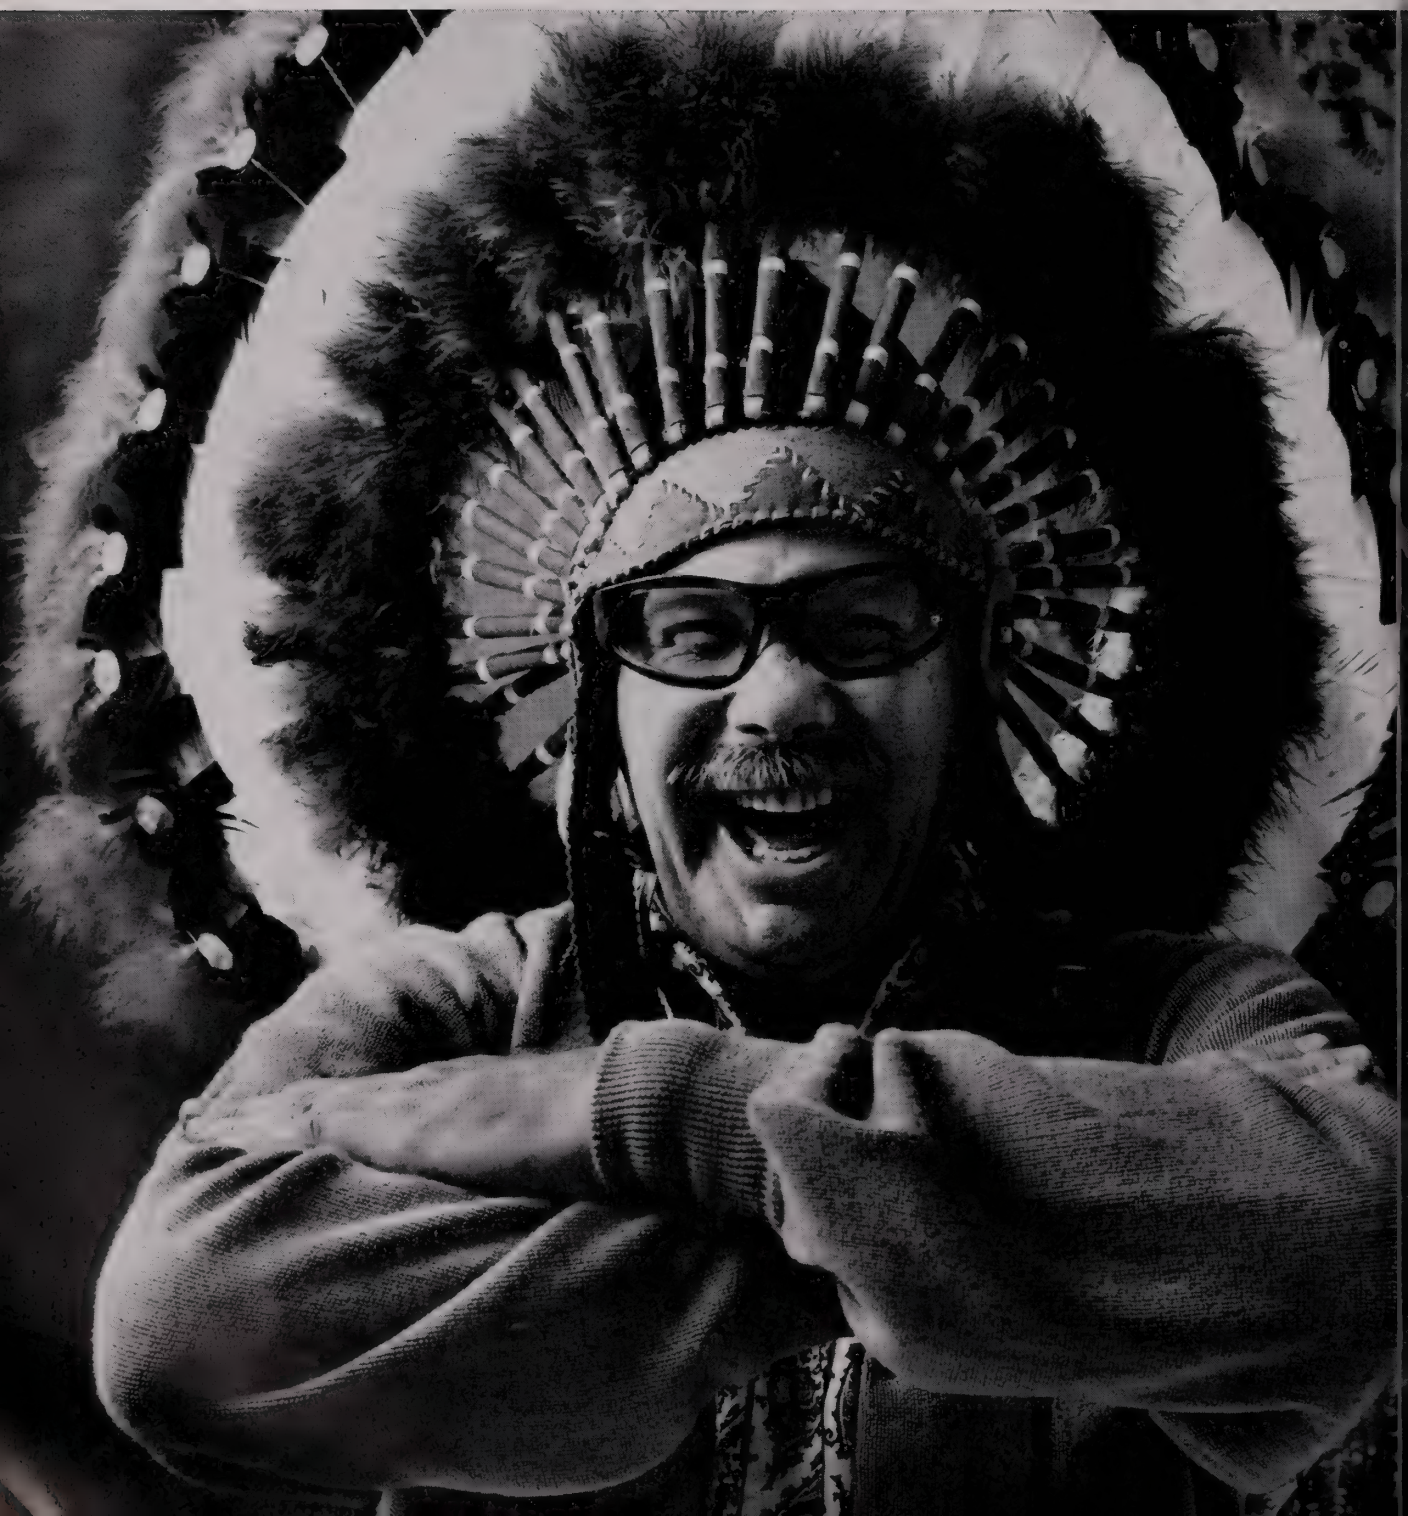
PRACTICAL AUTOMATION FOR THE CLINICAL LABORATORY—By Wilma L. White, Marilyn M. Erickson, and Sue C. Stevens, C. V. Mosby Co., St. Louis, 1968, 401 pages, $14.50.

What makes American technology go? Brainpower? Our educational system? Our organizational and managerial talents? Wealth? Resources? Or is it the computer? Take your pick, and you will be partly right. But only partly! According to Eric Hoffer, sage of San Francisco's waterfront, our skill at maintaining equipment forms the bedrock that supports our technocratic suprastructure.

We suspect he is right. After all, in this land teenage boys think little of taking apart and rebuilding car engines, many citizens successfully repair household appliances, and an army of men keep the wires open, eviscerate the innards of computers, and are at home with circuits, gears, fuses, switches, vacuum tubes, and transistors.



Yet in hospital laboratories, much automated equipment takes weeks to crank up, breaks down, or lies idle for want of maintenance. Why? Lack of a mechanical bent on the part of technologists and pathologists? Too much to do and too little time to do it? Fragile instruments pushed onto the market too soon? Neglect? Or is it because laboratory people fail to anticipate, to prevent, and to detect problems?

All, to a greater or lesser extent, contribute. But another headache is lack of a maintenance manual written by those who nurse their automated instruments through times of toil and trouble. This book should provide some relief.

Technologists and pathologists will gain practical information by dipping into the pages of this text, but physicians seeking a source book to help them interpret results for diagnosis or to digest data will find little to aid them. We recommend the book for its intended audience.

Richard C. Reece, M.D.
Minneapolis, Minnesota

He isn't burdened by his hypertension or his therapy...

Butiserpazide® lowers blood pressure so smoothly that patients are often untroubled by either the disease...or treatment

BUTISERPAZIDE provides not only the classic thiazide/reserpine formula; it supplements it with the mildly sedative effect of BUTISOL (butabarbital).

Clinical comparisons have shown that many patients respond to this treatment with (1) smooth, uniform lowering of blood pressure[1]...at times *below* the levels attained with previous therapy[2]; (2) "striking" improvement in such symptoms as headache, nervousness, palpitation and dizziness[2]; plus (3) "...lowered incidence of drug side effects."[2]

And BUTISERPAZIDE offers an added advantage: the usual dosage is just 1 tablet once or twice daily. It is available in two strengths for dosage flexibility.

Are there any hypertensives in *your* practice who might find life a little pleasanter on BUTISERPAZIDE?

Contraindications: Sensitivity to any component, porphyria, peptic ulcer, ulcerative colitis, mental depression, renal impairment or shutdown. **Warnings:** Consider the possibility of sensitivity reactions in patients with history of allergy or bronchial asthma. Coated potassium tablets, sometimes administered in conjunction with antihypertensive therapy, may be associated with small bowel lesions, which have led to obstruction, hemorrhage and perforation. Surgery has frequently been required and deaths have occurred. Such tablets should be used only when indicated and when adequate dietary supplementation is not practical. They should be discontinued immediately if abdominal pain, distention, nausea, vomiting, or g.i. bleeding occur. *Use in Pregnancy:* Exercise caution, since thiazides cross the placental barrier and may cause fetal or neonatal hyperbilirubinemia, thrombocytopenia or altered carbohydrate metabolism; adverse reactions seen in the adult may occur in the newborn. Use reserpine in women of child-bearing age only when essential to patient welfare. Increased respiratory secretions, nasal congestion, cyanosis, and anorexia may occur in infants born to reserpine-treated mothers. **Precautions:** *Butisol* (butabarbital)—Exercise caution in moderate to severe hepatic disease. Elderly or debilitated patients may react with marked excitement or depression. *Hydrochlorothiazide*—May induce electrolyte imbalance; when used with digitalis or one of its glycosides and in patients with severe hepatic insufficiency, cardiac arrhythmias or symptoms of impending hepatic coma may occur. Discontinue and institute appropriate countermeasures if prolonged use produces hypokalemia or (likely with sodium restriction) hyponatremia and hypochloremic alkalosis. (Ammonium chloride, used to reverse hypochloremic alkalosis, is contraindicated in hepatic disease.) May produce elevated serum uric acid levels (and, infrequently, gout) or reduce glucose tolerance, altering insulin requirements in diabetics. *Reserpine*—Observe for signs or symptoms of peptic ulcer or ulcerative colitis. Discontinue at first sign of mental depression; keep in mind possibility of suicide. Exercise extreme caution in history of mental depression. May produce cardiac arrhythmias when used with digitalis and quinidine, or may precipitate biliary colic in patients with gallstones. Discontinue 1 to 2 weeks before surgery; inform the anesthetist in event of emergency surgery. Exercise caution in history of epilepsy. Discontinue 1 to 2 weeks before ECT. *General*—Exercise caution in coronary artery disease. **Adverse Reactions:** Dizziness, drowsiness, weakness, nasal congestion, leg cramps, nausea, palpitations, superficial skin bruises, palmar erythema, headache, dehydration, skin rash, "hangover," systemic disturbances, diarrhea, itching, vomiting, paresthesia, photosensitivity, pancreatitis, jaundice, xanthopsia, purpura, thrombocytopenia, leukopenia, agranulocytosis, aplastic anemia, anorexia, gastric irritation, abdominal cramping, constipation, glycosuria, vertigo, cutaneous vasculitis, orthostatic hypotension (potentiated by alcohol, barbiturates, or narcotics), increased salivation and gastric secretion, increased intestinal motility, loose stools, angina-like syndrome, arrhythmias, bradycardia, flushing, hypotension, nervousness, paradoxical anxiety, rarely atypical Parkinsonian syndrome, central nervous system sensitization (manifested by dull sensorium, deafness, glaucoma, uveitis, optic atrophy), dryness of mouth, syncope, epistaxis, weight gain, and impotence or decreased libido. **Usual Adult Dosage:** BUTISERPAZIDE®-25 or BUTISERPAZIDE®-50: 1 tablet daily or b.i.d. When used with other antihypertensive agents reduce dosage of both drugs about 50% and observe carefully for changes in blood pressure. ***Before prescribing or administering, see package insert.*** **References:** **1.** Johnson, H. J., Jr.: Penna. M. J. **67**:35, 1964. **2.** Coodley, E. L.: Curr. Ther. Res. **4**:460, 1962.

Community Measles Clinics and the Physician

D. S. FLEMING, M.D.*
Minneapolis, Minnesota

A NATION-WIDE flood of measles vaccination campaign materials—including even Peanuts cartoon strips—issuing from the U.S. Public Health Service in the past few years cannot have escaped concern from members of the medical profession. Physicians are justifiably wary of such crash programs, especially in view of the near tragedies stemming from such recent events as the jaundice traced to yellow fever vaccine during World War II and the vaccine-related poliomyelitis cases of the "Cutter Incident." Nevertheless, the national measles eradication program has earned the support of nearly every concerned professional organization.

The fulfillment of school entry requirements for measles immunization should not, however, obscure the larger objectives of the measles eradication program of virtual elimination of all susceptibles in all age groups. County-wide public measles clinics have been conducted in over 50% of Minnesota's counties with a resulting large increase in vaccine utilization in both private physicians' offices and public clinics.

Background

Measles has been reportable in Minnesota since 1910 and Department of Health records show that reported incidence has ranged from an all-time high of 29,759 cases in 1935 to a low of 140 cases in 1967. Measles deaths have ranged from a high of 282 in 1923 to no deaths in 1964 and 1967. The average annual number of cases from 1954 through 1963 was 3,401; the average number of deaths was six.

Live attenuated measles virus vaccine was licensed in the U.S. in 1963 and was added to the Federal Vaccination Assistance Grant. Local projects in Minneapolis, St. Paul, and Rochester-Olmsted County began distributing the vaccine from federal sources in July, 1966. The state project began July 1, 1967, incorporating the dual objectives of (1) stimulation of measles immunization with vaccine pur-

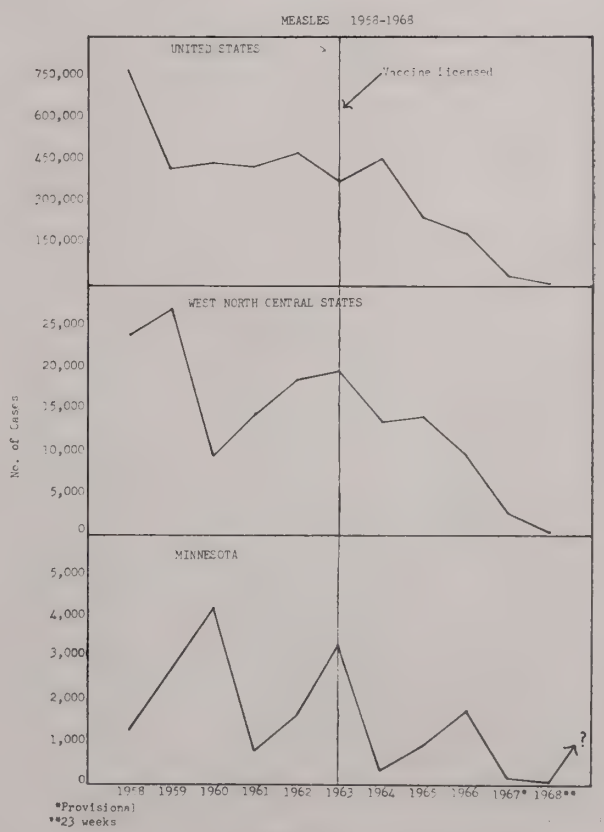

Figure 1

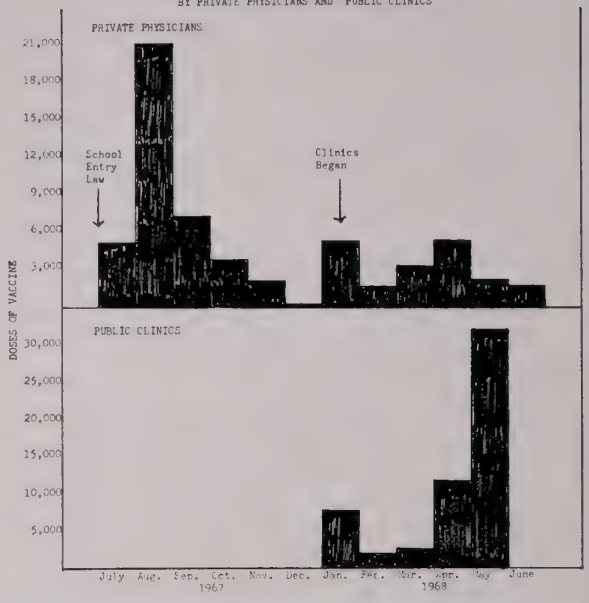
*Director, Division of Disease Prevention and Control, Minnesota Department of Health.

chased by both federal and state funds, and (2) the development of a newborn follow-up "maintenance" program to inform parents of the need for all the common immunizations at the appropriate age.

The Downward Trend

Figure 1 shows the reported measles cases in the U.S., the west-north central states, and Minnesota since 1958.[1] From this data two inferences may be drawn. First, the decline of measles in Minnesota reflects both the use of vaccine by Minnesota's physicians in the years 1963-66 and the general trend throughout the country. Second, an increase in the occurrence of measles in 1969 may be expected if the trend in Minnesota since 1963 continues.

Public Clinics in Minnesota



Many areas had already held measles clinics in the past few years, but additional scope and efficiency of these clinics became possible with the new capacity of the Department of Health to provide the working "tools," for example, the jet guns for economical and efficient injection of vaccine from multiple dose vials at rates of 600-800 doses per hour (Figure 2).

From January to May, 1968, 47 of Minnesota's 87 counties (Figure 3) conducted measles immunization clinics, nearly all with the use of the jet gun; a total of over 60,000 doses of vaccine were distributed in this way.

Table 1 shows the monthwise distribution of vaccine by clinics and by private physicians. It

TABLE 1

MONTH-WISE DISTRIBUTION OF MEASLES VACCINE BY PRIVATE PHYSICIANS AND PUBLIC CLINICS

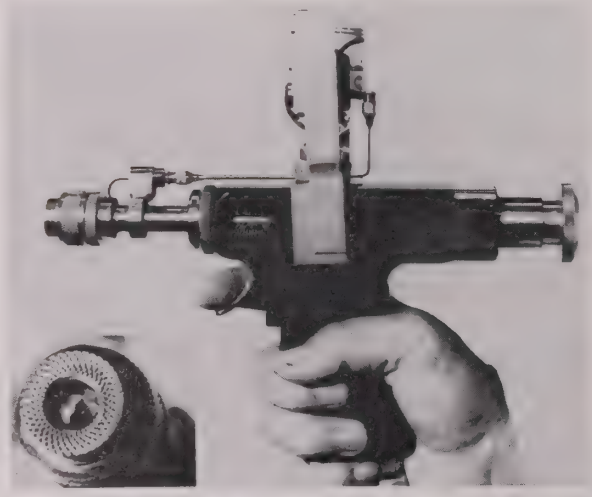


Figure 2

can be seen that a remarkable rise in vaccine utilization by private physicians occurred in response to the school entry legislation in the summer of 1967. This effect of mass clinics has been noted throughout the U.S.: that is, the balance between immunizations given privately and publicly does not change when a community promotes immunization with mass clinics.[3] Both groups experience an increased demand for services with a resulting improvement in community protection. Furthermore, the turnout for mass clinics has been shown to be greater when a small donation (25-50c) is asked than when the vaccination is "free," additional evidence that free services are not valued highly.

Theoretical Considerations

Every disease can be defined as distinctly by its epidemiologic characteristics as by its clinical or pathologic features. Because the epidemiology of measles is unique, unwarranted parallels between it and other common illnesses, for which effective vaccines have been used, may be misleading. In this regard, the possible danger of a susceptible adult population is

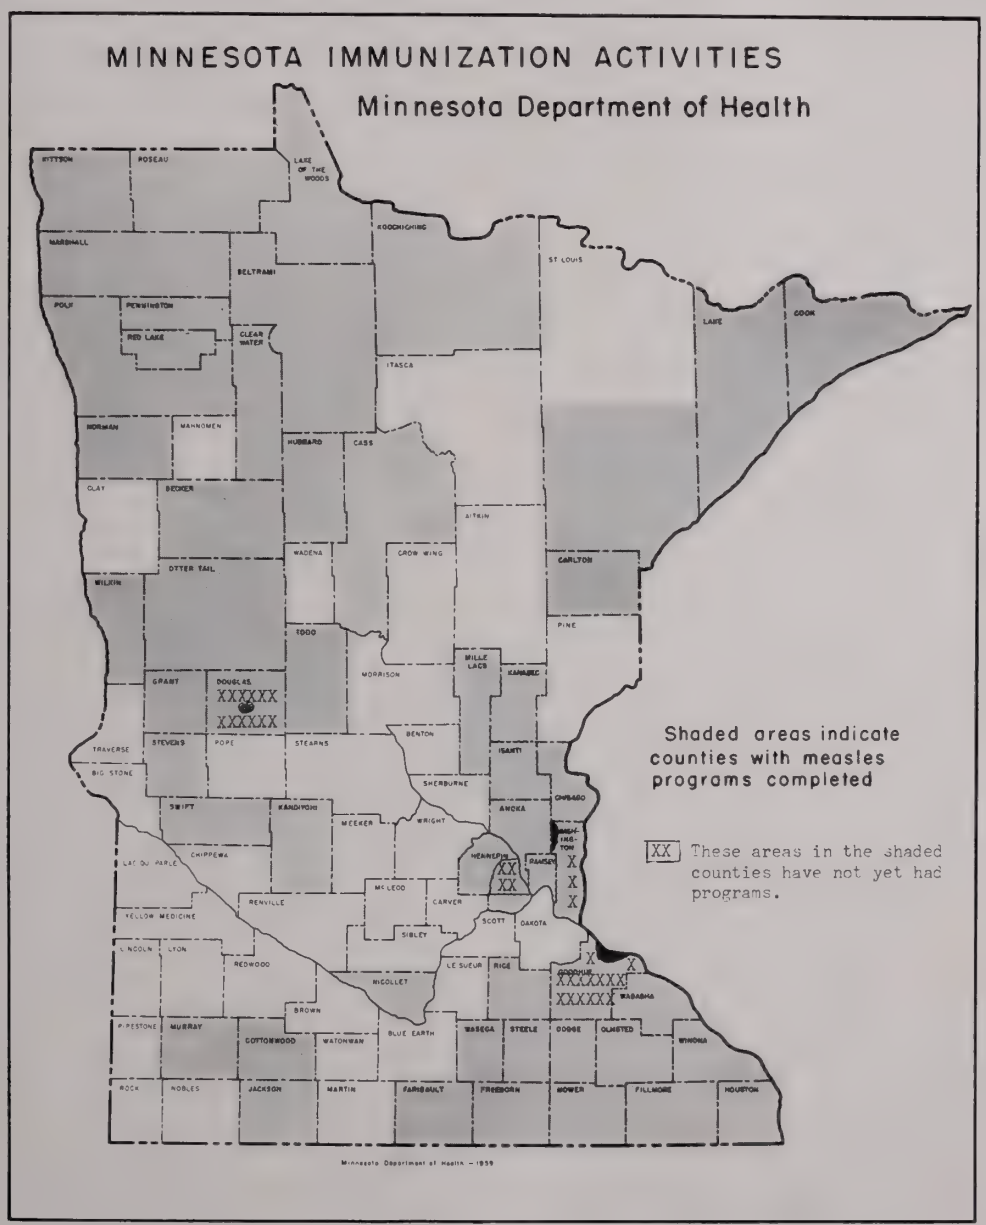

Figure 3

foremost.

The Immune Populace

Table 2 illustrates that the natural occurrence of measles results in the immunity of over 90% of a susceptible population by age 15 years. With widespread use of an effective vaccine and the subsequent dramatic decline in the occurrence of measles cases, the ultimate proportion of measles-immune adults will gradually fall, reflecting only the use of the vaccine. Vaccination of 60-75% of the population may be effective in preventing major outbreaks and therefore also in preventing the exposure of other unvaccinated susceptibles in childhood.

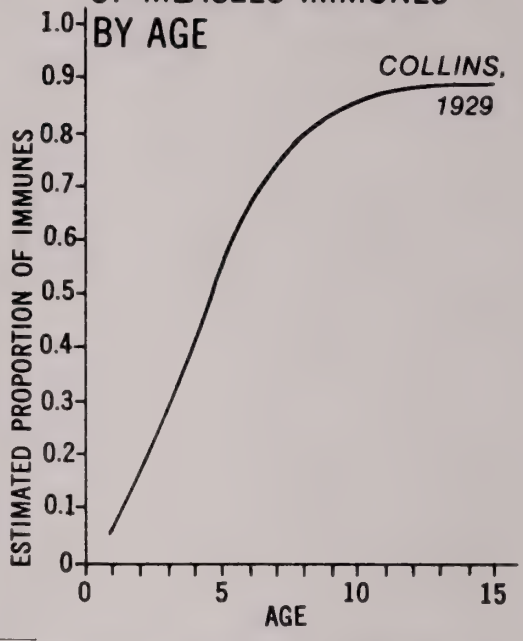
The Susceptible Population

A measles vaccination law may therefore provide a needed safeguard to prevent the repetition of the Faroe Island experience in which 50% of a susceptible population died during a measles epidemic.[4] More than one approach may be necessary, however, to reach all the objectives of the vaccination plan.

The shortcomings of a single approach have been suggested by a 1967 study in Hopkins County, Kentucky, with an experimental and a control group of infants demonstrating that letters sent to parents urging measles immunization through private physicians had no discernible effect on increasing the number immunized in the experimental over that in the control group.[5] At best, only about one half of the children one to two years of age were protected. Data of this nature is subject to the limitations of socioeconomic variables, but it is not encouraging.

Comments and Conclusions

The national commitment to measles eradication, however controversial as a priority or possibility, is an accomplished fact with implications for every state. On the one hand are the natural reactions of many physicians and taxpayers such as:



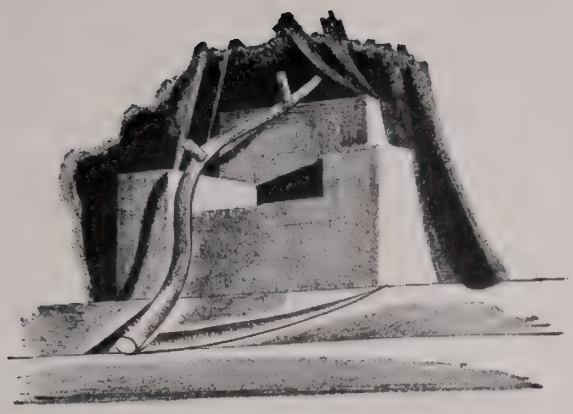
"Immunizations are the responsibility of the individual family and physician."

"Measles immunizations have been adequately done through private physicians' offices in this state."

"This is another government 'dole' ".

TABLE 2*

ESTIMATED PROPORTION OF MEASLES IMMUNES BY AGE



*Measles Eradication—1967, U. S. Public Health Service.

On the other hand is the reality of governmental assistance in money, supplies, and personnel to help achieve higher levels of immunization against many diseases. Fortunately Minnesota is achieving the objectives of both groups with mutual understanding and objectivity, and with practical benefits to all.

A Federal Vaccination Assistance Grant* has made possible the purchase of measles vaccine for every Minnesota child from age one to 12 years. Over 70,000 doses of this vaccine have been distributed in the first five months of 1968 through public clinics and private physicians' offices. Although compliance with the measles school entry requirement should eventually insure the vaccination of a large percent of the population, a current "one-time-only" approach through public clinics should be completed in 1968 if a resurgence of measles in 1969 is to be prevented and if we are to insure that a significant number of older children now in school but unaffected by the school entry law will not reach their adult years susceptible to the hazards of adult measles.

In Memoriam

All human things are subject to decay, And when fate summons, monarchs must obey.—DRYDEN

OSCAR B. BERGMAN, M.D.

Dr. O. B. Bergman, St. James physician for 40 years, died June 25. Born in Sweden, Dr. Bergman came to the United States at the age of one. He attended schools in Foley and St. Cloud and graduated from the University of Minnesota Medical School in 1924. After practicing in Janesville for two years, he went to St. James where he had since practiced.

Dr. Bergman was a member of the St. James school board for 18 years, the Lions Club, American Legion, American Medical Association, Blue Earth Valley Medical Society and a Life Member of the Minnesota State Medical Association.

He is survived by his wife and two daughters.

THOMAS LOWRY, M.D.

Dr. Thomas Lowry, 58, a Minneapolis physician and a clinical professor of medicine at the University of Minnesota, died August 7, due to an internal hemorrhage. He was born in Minneapolis and graduated from Princeton University and the Cornell University Medical School.

Dr. Lowry began practice in Minneapolis in 1939 and at that time joined the University of Minnesota medical staff. From 1950 to 1962 he served as medical director of General Hospital. At the time of his death, Dr. Lowry was a member of the board of directors of the Hennepin County Medical Society, and a member of the Minnesota Society for Internal Medicine, the Minnesota Academy of Medicine, the Minneapolis Society of Internal Medicine, the Minnesota Society for the Study of Diseases of the Heart and Circulation, the American Medical Association and the Minnesota State Medical Association. The Minneapolis Medical Research Foundation, Inc., the reserach arm of General Hospital, was begun under his direction.

He is survived by his wife, Dr. Elizabeth Lowry, two sons and three daughters.

ARRAH B. EVARTS, M.D.

Dr. Arrah Evarts, 89, Rochester physician died April 3. She was born in Dodge Center and obtained her medical degree at the Minneapolis College of Physicians and Surgeons, Hamline University.

She retired June 1, 1936, from the staff of the Rochester State Hospital where she was senior assistant physician. She had joined the staff of the Hospital in 1918. Previous to that time she had served six years as a member of the staff of St. Elizabeth's Hospital, District of Columbia.

She was a member of the American Medical Association, and the Zumbro Valley Medical Society and a 50 Club and Associate Member of the Minnesota State Medical Association.

JAY C. DAVIS, M.D.

Dr. Jay Davis, 68, Minneapolis physician, died May 31. Born in Ogden, Iowa, Dr. Davis received his medical degree from the University of Minnesota. He was a former associate in the Department of Medicine at the Minneapolis General Hospital and a member of the faculty of the Department of Medicine at the University of Minnesota Medical School. Dr. Davis was an authority on methods for detecting bile pigments in the blood and was widely known in connection with diseases with liver and blood.

He was a member of the American Medical Association and the Hennepin County Medical Society and an Associate Member of the Minnesota State Medical Association.

He is survived by his wife.

CHARLES WILLIAM MAYO, M.D.

Dr. Charles W. Mayo, emeritus senior surgeon of the Mayo Clinic and representative of the third generation of Mayos to practice in Rochester, died July 28, of injuries sustained when his automobile left a country road in Rochester.

Born in 1898, the son of Dr. Charles Horace Mayo and Edith Graham Mayo, he was educated in a public

Charles William Mayo, M.D.
(Continued)

school in Rochester. His degree of bachelor of arts was obtained from Princeton University and that of doctor of medicine from the University of Pennsylvania. In 1927 he returned to Rochester as a fellow in surgery of the Mayo Graduate School of Medicine. He was appointed consulting surgeon and head of a section in general surgery in the Mayo Clinic in 1931, and in 1932 was appointed an instructor in surgery in the Mayo Graduate School of Medicine. Later he was advanced to assistant professor in 1935, associate professor in 1940 and professor in 1947. He became senior surgeon of the Mayo Clinic in 1960 and in 1963 retired from the Mayo Clinic.

The contributions of Dr. Charles Mayo encompassed many facets of life. He met the personal challenge of living up to a famous family name in the medical profession, taking on the broader modern responsibilities of that profession and of his role in the Mayo Clinic.

He moved increasingly into public service, giving generously of his time and concern. He supported the University of Minnesota in many ways. He was a board member and chairman of the regents. He served as an alternate United States delegate to the United Nations and as president of the American Association for the United Nations. Practically every nation in the world has conferred honorary degrees on Dr. Mayo. He was a member of many medical societies and associations and had been honored by universities all over the United States and the world.

Dr. Mayo was a gifted educator, author, editor and public servant. His accomplishments were many; his honors and recognitions too many to list, but perhaps the greatest of all, was Dr. Mayo's concern for individuals—their feelings, condition, rights and future.

LAWRENCE J. LEONARD, M.D.

Dr. Lawrence J. Leonard, 74, Minneapolis physician, died August 31. A native of Jordan, Minnesota, Dr. Leonard received his medical degree from Creighton University in Omaha and was licensed to practice medicine in Nebraska in 1916. He established a clinic in 1922 in North Minneapolis.

In the half century he served in the medical field, Dr. Leonard's special interest had bent toward allergies, gastrointestinal diseases, hypnosis and medical-legal problems.

Dr. Leonard was a member of the American Medical Association and the Hennepin County Medical Society and a 50 Club and Life Member of the Minnesota State Medical Association.

He is survived by his wife and one son, Dr. Lloyd F. Leonard.

NELSON W. BARKER, M.D.

Dr. Nelson Waite Barker, a member of the staff of the Mayo Clinic for 36 years, emeritus head of a section of medicine and chairman of two sections of medicine, died August 21, after a fall in his home.

Born on April 25, 1899, at Evanston, Illinois, Dr. Barker received his degree of doctor of medicine from the Rush Medical College of the University of Chicago. He came to Rochester in 1926 as a fellow in medicine.

Dr. Barker was certified as a specialist in internal medicine by the American Board of Internal Medicine, he was a diplomate of the National Board of Medical Examiners, a fellow of the American College of Physicians and a member of the Council on Circulation and the Council on Arteriosclerosis of the American Heart Association. He also was a member of the Minnesota Society of Internal Medicine, the Southern Minnesota Medical Association, the Zumbro Valley Medical Society and Associate Member of the Minnesota State Medical Association.

He was president of the staff of the Mayo Clinic in 1955.

He is survived by his wife, one daughter and two sons.

GEORGE L. BERDEZ, M.D.

Dr. George L. Berdez, 77, Duluth pathologist for 45 years, died August 19. A native of Lausanne, Switzerland, he was graduated from the University of Lausanne's Medical School and come to the United States in 1922.

He was the author of numerous medical books and papers on clinical pathology. Dr. Berdez was a member of the American Medical Association, the St. Louis County Medical Society, the American College of Pathologists, the Duluth Surgical Society, the Duluth Interurban Academy of Medicine and a Life Member of the Minnesota State Medical Association.

He is survived by five sisters.

JOHN F. ZACHMAN, M.D.

Dr. John F. Zachman, 39, Melrose physician, died August 26. He was born in Melrose and had spent most of his life in that community.

Dr. Zachman had a degree from the School of Forestry of the University of Minnesota but later entered the School of Medicine and received his medical degree in 1959.

He was a member of the American Medical Association, Stearns-Benton County Medical Society and the Minnesota State Medical Association.

His wife and two sons survive him. Dr. A. H. Zachman of Melrose is his father.

JOHN WILLIAM STUHR, M.D.

Dr. John W. Stuhr, 85, Stillwater physician, died July 30. Born in Euclid, Minnesota, Dr. Stuhr attended Macalester College and received his medical degree from the University of Minnesota in 1917. He interned at Ancker Hospital, St. Paul, and came to Stillwater in 1920 after serving as a lieutenant in the Navy Medical Corps in World War I.

He was a fellow of the American College of Surgery, a member of the Washington County Medical Society and American Medical Association and a 50 Club and Life Member of the Minnesota State Medical Association.

He is survived by his wife.

University of Minnesota

Minnesota Medical Foundation

Eivind O. Hoff, Jr.

An organization's growth is frequently the direct result of the initiative and foresight of an individual. This is true of the Minnesota Medical Foundation. An organization that has grown in the past eight years to a membership of 2,000 and which has acquired assets of five million dollars, the Foundation reflects the dedication and response to human problems exhibited by its present director, Eivind O. Hoff, Jr. The recent history of the Foundation is, for the most part, a tale of this man's personal managerial abilities and fund-raising skill.

The Minnesota Medical Foundation was chartered in 1939 to encourage private support of the University of Minnesota Medical School. In the succeeding eleven-year period membership more than doubled, from 415 to 851, and the Foundation accrued assets of better than $42,000. Up to that time, $81,000 had been donated through the Foundation for support of various

medical activities at the University of Minnesota. It was in 1959 that Eivind Hoff assumed the directive reins of the Foundation as the first full-time director. Thus began a new period of growth.

Mr. Hoff was a product of Mountain Lake, Minnesota, but received his high school diploma at Brainerd. After serving for a while as a U.S. Coast Guardsman, he entered the University of Minnesota, where he received the bachelor of arts degree in journalism, and then returned to active duty with the Navy for the latter part of the Korean conflict.

Mr. Hoff's communications career began in the world of sport—as sports publicity writer for the Minneapolis Park Board. In September of 1963 he moved to the position of publicity director for the Minneapolis Lakers basketball team. This "liberal education" helped him develop the art of dealing with news media during an era that was glamorous with the names and deeds of famous athletes.

The year 1955 saw Hoff moving from the Lakers and the sports world to the more sedate but ultimately equally exciting world of medical communications, where he assumed the responsibilities of public information director for the Minnesota Heart Association. It was here that Mr. Hoff encountered man's "most sensitive nerve," his pocketbook, and he insists he is still learning the techniques of extracting private monies for good causes. "It is decidedly not an exact science," he says. With the Heart Association, Hoff helped produce educational television programs on heart research for KTCA, Channel 2. Though he was the producer, he also found himself "acting" in some TV segments and is still seen occasionally in playbacks of these former productions screened for classroom viewing.

Mr. Hoff's potential was again challenged in 1959 when he was selected over 30 other applicants to serve as the first full-time director of the Minnesota Medical Foundation, a position created by the Trustees of the Foundation to implement its growth in new directions. His inventiveness served the Foundation well, as attested to by the growth figures in more than just dollars. He has been instrumental in implementing new programs and ideas, thus expanding the concept of the Foundation far beyond its original bounds of 1939. In 1959 the Foundation moved rapidly into fund-raising; into student relations; and, by means of activities coordinated with those of the Minnesota Medical Alumni Association, into alumni work. By 1961, membership dues from alumni and others were providing the operating funds of the Foundation, so that total contributions and bequests could go to the specific projects for which they were intended.

The Foundation has given nearly ten million dollars for Medical School purposes. Of its total assets as of June 1967, more than 85% were direct endowments. Today the Foundation grants more than one quarter million dollars annually for various purposes. The funds accrued through Mr. Hoff's diligent work and the activities of a dedicated Board have stemmed from a remarkable variety of sources throughout the Midwest and the United States. The $200,000 legacy of a North Dakota farmer now endows the Foundation's medical research program which encourages research by medical students and young faculty members. The construction of Diehl Hall, the new facility for the Bio-Medical Library, was aided through a gift of $25,000 from the Foundation. In 1967 a bequest from the estate of Royal A. and Olive W. Stone of St. Paul established an endowment for research in heart disease and cancer. The Foundation claims more than 3,000 alumni and lay members.

Mr. Hoff is also executive editor of the Medical Bulletin of the University of Minnesota, an alumni magazine which emphasizes strong ties among the Medical School's faculty and its graduates. "Keen interest in the Alumni Notes section of the Bulletin," says Mr. Hoff, "is an expression of latent affection for 'Alma Mater' which the Medical School must capitalize on." The Bulletin is circulated to more than 5,000 medical alumni of the University.

It is Mr. Hoff's opinion that the finest achievement of the Foundation is that of providing scholarships for medical students at the University. The first awards of $500 were granted in 1949. Through 1967, 678 scholarships totaling more than $330,000 had been distributed to deserving students.

Today the Foundation scholarship program assists 12% of the medical student body. Most of this money is expected to be contributed back to the school in future alumni gifts. Mr. Hoff predicts the time is not far distant when a Foundation scholarship will be available to every student in the Medical School. He also envisions the possibility of a tuition-free Medical School supported by the Foundation, certainly a worthwhile if perhaps somewhat unrealistically ambitious objective.

Personal contact is Mr. Hoff's forte. As director of the Foundation, he has established admirable rapport with administrators, medical professionals and students alike. His contemporaries are motivated by his inventiveness in making others feel ideas have originated within themselves. His office has become a meeting place for medical students seeking advice and counsel or just an ear to bend.

Through his many abilities and applied techniques, Eivind Hoff has done much to place the Minnesota Medical Foundation on a new level of service to the Medical School, to the University, and to the State of Minnesota. Its success is a story of his own goals and of those of the Medical School of the University of Minnesota.

Robert B. Howard, M.D.*
Minneapolis, Minnesota

*Dean, University of Minnesota Medical School.

Bloodletting Schedule

By the seventeenth century bloodletting had become pitiless. Guy Patin reports that he bled his wife twelve times for a fluxion* in the chest, his son twenty times for a continued fever, himself seven times for a cold in the head, and two friends thirty-six and sixty-four times each for fever and rheumatism respectively. The technique of the practice became highly specialized. Schedules of propitious times for bleeding were common from the days of Salerno. The list of appropriate days for bleeding recorded in the Bible of the Degge family of eighteenth century Virginia is:

"April, to let blood on the left Arm on the 3rd, 12th, or 15th, but the head of bleeding on the 7th, 8th, 10th, and 20th.

"May, This month to let blood on the 1st, or 8th, 10th and 27th, or 28th. But take heed of the 2nd, 5th, and 6th. It will be harmful.

"June, to bleed do it on the 28th day. Take heed not to bleed on 7th, 10th, 16th, 18th, or 20th."

And so on for the remainder of the year.†

*Fluxion—discharge.
†Bernhard Stern: Society and Medical Progress, 1941.

This advertisement for TAO® (triacetyloleandomycin), published at the request of the Food and Drug Administration, replaces a recent one which the FDA regards as misleading.

The advertisement headlined "new evidence for TAO . . ." and emphasized that the drug is "for the frequently seen respiratory infection in the office and for a problem pathogen* in the hospital. *Staphylococcus aureus."

We emphasize that triacetyloleandomycin is to be used only for acute, severe bacterial infections where adequate sensitivity testing has demonstrated susceptibility to this drug and resistance to other less toxic agents. In view of the possible, but reversible, jaundice and hepatotoxicity of this drug, other less toxic agents should be used unless the organism is resistant to those agents, or in those cases where hypersensitivity precludes their use.

TAO is contraindicated in preexisting liver disease or dysfunction, and in individuals who have shown hypersensitivity to the drug.

The advertisement emphasized that no tooth staining has been reported after ten years of use of this antibiotic. The Food and Drug Administration regards this claim as an implied comparison suggesting that triacetyloleandomycin and tetracycline have a similar antibacterial spectrum of effectiveness, and that TAO has less toxic potential. Any such implication is not intended and, of course, would be invalid.

The advertisement referred to a research study in which patients were given triacetyloleandomycin prior to determining the susceptibility of the offending organism. Any suggestion that triacetyloleandomycin be used clinically without first determining susceptibility of the offending organism should be disregarded.

NEW YORK, N.Y. 10017

TAO®(triacetyloleandomycin)
Brief Summary

INDICATIONS: Include streptococci, staphylococci, pneumococci and gonococci. Recommended for acute, severe infections where adequate sensitivity testing has demonstrated susceptibility to this antibiotic and resistance to less toxic agents.

CONTRAINDICATIONS: Contraindicated in pre-existing liver disease or dysfunction, and in individuals hypersensitive to the drug.

PRECAUTIONS: CAUTION: USE OF THIS DRUG MAY PRODUCE ALTERATIONS IN LIVER FUNCTION TESTS AND JAUNDICE. CLINICAL EXPERIENCE AVAILABLE THUS FAR INDICATES THAT THESE LIVER CHANGES WERE REVERSIBLE FOLLOWING DISCONTINUATION OF THE DRUG.

Not recommended for prophylaxis or in the treatment of infectious processes, which may require more than ten days continuous therapy. In view of the possible hepatotoxicity of this drug when therapy beyond ten days proves necessary, other less toxic agents should be used. If clinical judgment dictates continuation of therapy for longer periods, serial monitoring of liver profile is recommended, and the drug should be discontinued at the first evidence of any form of liver abnormality. When treating gonorrhea in which lesions of primary or secondary syphilis are suspected, proper diagnostic procedures, including dark-field examinations, should be followed. In other cases in which concomitant syphilis is suspected, monthly serological tests should be made for at least four months. When used in streptococcal infections, therapy should be continued for ten days to prevent the development of rheumatic fever or glomerulonephritis. The use of antibiotics may occasionally permit overgrowth of nonsusceptible organisms. A resistant infection or superinfection requires reevaluation of the patient's therapy. In the event such occurs with this drug the medication should be discontinued, and specific antibacterial and supportive therapy instituted.

ADVERSE REACTIONS: Although reactions of an allergic nature are infrequent and seldom severe, those of the anaphylactoid type have occurred on rare occasions.

The James E. Moore Society

Origin and Purpose

THE JAMES E. MOORE SOCIETY traces back to discussions within the Department of Surgery approximately ten years ago. Since early post-World War II days the Department had sponsored a Quarterly Seminar in Surgical History—with Richard Lillehei's energetic, ardent, and wise leadership contributing to that effort. Each quarter of the school year 20 to 25 members of the Department assembled for dinner at the Campus Club and then repaired to the Mayo Auditorium for an evening lecture. In consequence, a keen and abiding interest in the History of Medicine was generated and took firm root in many of the Surgical Staff.

Student Participation

In time it became increasingly apparent that a similar function with active participation at the student level would have a potentially greater influence in creating within the Medical School a manifest and continuing interest in Medical History. It was J. B. Aust who crystalized deliberation into action and achievement in the school year 1961-62.

The student membership is a self-perpetuating organization, its participants chosen largely from the Junior Class in Medicine on the basis of scholarship, evidence of interest in Medical School matters beyond the required curriculum, and an affinity for Medical History and one another: constituting a fairly homogeneous group of the most talented and highly motivated students in the upper two classes of the School. This group of approximately 20 students meets once a month at the homes of faculty members of the Department of Surgery, joined by a few representatives of the staff. Dr. Mead Cavert, Associate Dean, has taken a keen interest in these sessions, and Leonard Wilson, Professor of Medical History, is providing enthusiastic support.

Choice of a Name

Anyone studying the history of the Medical School will quickly learn that a significant role in its development was played by Dr. Moore, a member of the Surgical staff from 1888 until 1904 when he became Professor of Surgery. He was essentially the builder of the Department—fervently interested in teaching and ambitious for the School's success and progress: a source of robust strength to the Medical School and the Department of Surgery.

Therefore it was with good reason that members of the Department of Surgery chose the name of James E. Moore to adorn this student organization with its special focus on Medical History.

Renewal of Interest in Medical History

Since student days a favorite theme of mine has been that if every teacher in the School from Anatomy to Zoology provided in his lectures a historical background of his subject matter, more effective teaching would result, since there is probably no keener incentive to scholarship in any discipline than a study of its evolution. Fielding Garrison has said that the best approach to Medical History is for the student "to back into it." What Garrison doubtless meant was that the student should not attempt to launch a systematic frontal attack upon the entire field but direct his maiden efforts at assessment of an isolated problem in a restricted area. Acquiring an acquaintance with the origins of the surgical procedures in my field made me, I feel certain, a more effective teacher than limiting my interest to the current scene. It has surprised and occasionally shocked me that some of our best students show little or only perfunctory interest in the literature of Medicine older than a decade and none for that prior thereto.

In recent years, however, there has been a gratifying resurgence of interest in Medical History among medical schools that hopefully will restore its teaching to the curriculum.

The James E. Moore Society is beginning to make its influence felt at Minnesota; its baptismal exposure to the fascination of Medical History should and undoubtedly will leave an indelible impress upon its participants. The time is not far off, I trust, when in both School and Community, in Gown and Town, there will arise a warm, palpable, flourishing interest in Medical History. That, after all, constitutes the most durable imprint and the most telling criterion of the success of the educative process.

Owen H. Wangensteen, M.D.*
Minneapolis, Minnesota

Editor's Note: With this issue a Student Section under the heading "The James E. Moore Society" will become a regular feature of MINNESOTA MEDICINE. A Student Editor has been appointed to the Board of Editors.

NORTHLANDS REGIONAL MEDICAL PROGRAM

REGIONAL PROGRAM FOR HEART DISEASE, CANCER AND STROKE

Distribution of Physician Services

THE PROBLEM of the distribution of medical care personnel and facilities was brought into critical focus with the declaration by our society that modern medical services should be equally accessible to all persons. The Regional Medical Program Act was passed to stimulate better cooperative arrangements among health professionals to seek solutions to the problems of unequal medical care services.

Now that the fundamental duty of the medical profession to provide health care services to people has been re-emphasized, we need to analyze the nature of the problem of distribution. The cursory analysis described below embodies the following premises, which represent basic needs:

1. Functionally, the need for physician services may be assumed to be directly proportional to the number of people, the incidence of illness and death, and the number of hospital beds.
2. An unmet need exists for accurate morbidity data, but accurate data on the other parameters listed above are available.
3. The need for specialist services is greater in hospital practice and in areas with the highest death rates.
4. Occasionally, patients will travel long distances for medical services, but accessibility within reasonable driving distance is demanded for most services. Accessibility corresponds roughly with the economic subdivisions of the state.
5. People have come to recognize and demand the modern medical services and facilities which modern medical science has developed.
6. Recently, an inordinately large number of physicians (especially specialists) have located in or near large medical centers. Medical service problems are therefore intensified.

As a partial analysis of the problem, I have computed the following summary from available objective data:

	Medical Center Areas (7 County Metropolitan Area and Olmsted County)	**Remainder of State**	Area A (7 Counties NW Section)
% of Total Population	49	51	4.4
% of All Hospital Beds	56	44	4.6
% of All Deaths	43	57	5.1
Death Rate	7.9	10.2	10.75
% of All Doctors	68	32	2
Population per Doctor	650	1400	1979
Hospital Beds per Doctor	3.6	6	10.3

Deaths per Doctor per year	3.6	10	21
% of All Specialists	80	20	1
Population per Specialist	870	3500	6252
Hospital Beds per Specialist	5	15	56
Deaths per Specialist per year	7	36	67

The data for Area A (Northwest) show the greatest evidence of maldistribution, but those from Areas C, D and E (Central and Southwest) are similar. All peripheral areas show significant deprivation.

Deaths from heart disease, malignant neoplasms and cerebral vascular disease constituted 66.3% of all deaths, and the separate rates were proportionate to total rates in all areas. (1965 and 1966 data). The elevated total death rates show the increased need for all services in peripheral areas.

Specialists include all physicians claiming to be full-time in any specialty. (American Medical Association data.) The magnitude of maldistribution of specialists is clearly evident. Now that virtually all medical graduates specialize, the distribution problem may be expected to become progressively more acute.

Several uncontrolled variables are recognized: the younger average age of the population in the Medical Center Areas; the effects of patients coming from or going to out-of-state areas for medical services; physicians engaged primarily in administration, public health, industry, teaching and research; general practitioners who function as specialists. Quantification of these variables is fundamentally desirable. However, adjustment of the data from quantification of variables would probably not adequately explain the maldistribution. Specifically designed action programs are clearly needed to solve medical service needs.

What is the answer to this problem? . . . Production of more general practitioners? Development of new family practice specialists? Helicopter transportation of patients to large Medical Centers? Rapid transportation of Center specialists to peripheral areas? Development of rural extensions of large Medical Centers? Expansion of multidisciplinary group practices in towns which are economic area trade centers? Some of each of these?

How can we in the Medical Profession lead in finding solutions which will satisfy public needs and demand?

Winston R. Miller, M.D.
Program Director

Homo Sapiens

Men are very queer animals—a mixture of horse-nervousness, ass-stubbornness and camel-malice.—T. H. Huxley

---

This is another year when it won't be necessary to fool all the people all the time—only in the fall election campaigns.

What I mean is this—all good doctors must be primarily enthusiasts. They must have, like writers and painters, and priests, a sense of vocation—a deep-rooted, unsentimental desire to do good.—Noel Coward

---

The driver is safer when the roads are dry; the roads are safer when the driver is dry.

Manufacturers of ethical pharmaceuticals since 1856

In mere seconds your receptionist hands you every reference in your file on the Guillain-Barre syndrome.

You have a problem: no matter how faithfully you read your professional journals, you still waste hours tracking down the article you need now.

Forget it!

New Instadex frees you from searching out key reference information. In seconds your receptionist can hand you summaries of all the right articles from every journal you follow. You can then go straight to the article that interests you and spend your time reading instead of searching.

HOW TO TURN YOUR RECEPTIONIST INTO AN INSTANT INFORMATION RETRIEVER

Instadex was developed by a practicing internist who discovered—just as *you* have—that he was spending too much time hunting down half-remembered reports. Based on *Index Medicus'* subject analysis, this new system is so completely cross-indexed you cannot miss finding the article you want.

What's more, Instadex reaches you ready for immediate use. *You* do no processing or arranging. Instadex requires *no* filing. (Your girls will bless you for that!) In fact, Instadex supplements or completely replaces whatever card file you now maintain.

If the Instadex system saves you just four hours a *year* it will have paid for itself! We'll bet it'll save you four hours a month . . . or even more.

Ask your receptionist to write today for detailed information and prices. Why waste time fishing for information when you've other fish to fry?

Geigy

Regroton®

chlorthalidone 50 mg.
reserpine 0.25 mg.

One Regroton tablet a day usually helps you and your patient bring high blood pressure down and keep it down.

Regroton produces a smooth, long-acting effect that usually reduces both systolic and diastolic pressures. At the same time it often acts to allay anxiety and nervous tension associated with hypertension.

Although Regroton is generally well tolerated, adverse reactions may occur. This drug is contraindicated in mental depression, demonstrated hypersensitivity, and most cases of severe renal or hepatic diseases. For a complete list of side effects, please see the Prescribing Information summarized on the following page.

Regroton®

chlorthalidone 50 mg.
reserpine 0.25 mg.

One Regroton tablet a day usually helps you and your patient bring high blood pressure down and keep it down.

Indications: Hypertension. **Contraindications:** History of mental depression, hypersensitivity, and most cases of severe renal or hepatic diseases. **Warning:** With the administration of enteric-coated potassium supplements, which should be used only when adequate dietary supplementation is not practical, the possibility of small-bowel lesions (obstruction, hemorrhage, and perforation) should be kept in mind. Surgery for these lesions has frequently been required and deaths have occurred. Discontinue coated potassium-containing formulations immediately if abdominal pain, distention, nausea, vomiting, or gastrointestinal bleeding occur. Discontinue one week before electroshock therapy, and if depression or peptic ulcer occurs. *Use in pregnancy:* Because chlorthalidone may cross the placental barrier and appear in cord blood and thiazides may appear in breast milk, this drug should be used with care in pregnant patients and nursing mothers. When used in women of childbearing age, the potential benefits of the drug should be weighed against the possible hazards to the fetus. Use of chlorthalidone may result in fetal or neonatal jaundice, thrombocytopenia, and possibly other adverse reactions which have occurred in the adult. Increased respiratory secretions, nasal congestion, cyanosis and anorexia may occur in infants born to reserpine-treated mothers. **Precautions:** Antihypertensive therapy with this drug should always be initiated cautiously in postsympathectomy patients and in patients receiving ganglionic blocking agents, other potent antihypertensive drugs, or curare. Reduce dosage of concomitant antihypertensive agents by at least one-half. To avoid hypotension during surgery, discontinue therapy with this agent two weeks prior to elective surgical procedures. In emergency surgery, use, if needed, anticholinergic or adrenergic drugs or other supportive measures as indicated. Because of the possibility of progression of renal damage, periodic kidney function tests are indicated. Discontinue if the BUN rises or liver dysfunction is aggravated. Hepatic coma may be precipitated. Electrolyte imbalance, sodium and/or potassium depletion may occur. If potassium depletion should occur during therapy, the drug should be discontinued and potassium supplements given, provided the patient does not have marked oliguria. Take particular care in cirrhosis or severe ischemic heart disease and in patients receiving corticosteroids, ACTH, or digitalis. Severe salt restriction is not recommended. Use cautiously in patients with ulcerative colitis or gallstones (biliary colic may be precipitated). Bronchial asthma may occur in susceptible patients. **Adverse Reactions:** The drug is generally well tolerated. The most frequent side effects are nausea, gastric irritation, vomiting, diarrhea, constipation, muscle cramps, headache, dizziness and acute gout. Other potential side effects include angina pectoris, anxiety, depression, bradycardia and ectopic cardiac rhythms (especially when used with digitalis), drowsiness, dull sensorium, hyperglycemia and glycosuria, hyperuricemia, lassitude, restlessness, transient myopia, impotence or dysuria, orthostatic hypotension which may be potentiated when chlorthalidone is combined with alcohol, barbiturates or narcotics, leukopenia, aplastic anemia, skin rashes, thrombocytopenia, agranulocytosis, nasal stuffiness, increased gastric secretions, nightmare, purpura, urticaria, ecchymosis, weakness, uveitis, optic atrophy and glaucoma, and pruritus. Eruptions and/or flushing of the skin, a reversible paralysis agitans-like syndrome, blurred vision, conjunctival injection, increased susceptibility to colds, dyspnea, weight gain, decreased libido, dryness of the mouth, deafness, anorexia, and pancreatitis when epigastric pain or unexplained G.I. symptoms develop after prolonged administration. Jaundice, xanthopsia, paresthesia, photosensitization and necrotizing angiitis are possible. **Average Dosage:** One tablet daily with breakfast. **Availability:** Pink, single-scored tablets in bottles of 100 and 1000.

Minnesota State Board of Medical Examiners

Resolutions Adopted

on

July 12, 1968

BE IT RESOLVED, that Minnesota State Board of Medical Examiners proposes that the Rules and Regulations of Minnesota State Board of Medical Examiners be amended in the following particulars:

1. ME 2 (a), by striking and deleting therefrom the words "(which shall consist of both a written and oral or practical examination, as provided in ME 3)".

2. ME 2 (b) (2), by striking and deleting therefrom the words "oral or practical" and by substituting in lieu and in place thereof the word "licensing".

3. ME 2 (c), by striking and deleting therefrom the words "and who desires to take the oral or practical examination,".

4. ME 2 (e), by striking and deleting therefrom the words "both the written and oral or practical examinations" and by substituting in lieu and in place thereof the words "the licensing examination".

5. ME 3 (a), by striking and deleting therefrom the words "Examinations administered by the Board shall be both written and oral or practical.".

6. ME 4 (c), by striking and deleting the whole thereof.

7. ME 4 (d), by renumbering the same ME 4 (c).

8. ME 5 (c), by striking and deleting the whole thereof.

9. ME 5 (d), by renumbering the same ME 5 (c).

10. ME 11 (d), by striking and deleting therefrom the words "shall be both oral and written and".

BE IT FURTHER RESOLVED, that a public hearing on the adoption of the foregoing proposed changes in the Rules and Regulations of the Minnesota State Board of Medical Examiners be held on Saturday, November 9, 1968, at ten o'clock a.m., in Room 496 Lowry Medical Arts Building, Saint Paul, Minnesota.

BE IT FURTHER RESOLVED, that notice of such meeting shall be given by the Secretary of this Board pursuant to the provisions of Minnesota Statutes 1967, § 15.0412.

Bror F. Pearson, M.D.
President, Minnesota State Board
of Medical Examiners

J. P. Medelman, M.D.
Secretary-Treasurer, Minnesota State
Board of Medical Examiners

AMA

22ND CLINICAL CONVENTION

MIAMI BEACH

DECEMBER 1-4, 1968 · CONVENTION HALL

. . . the American "Riviera." Where glittering luxury hotels tower above glamorous Collins Avenue; and medicine, sea and sunshine mix in a delightful subtropical setting.

Register now, and be on hand for the world's largest winter medical meeting—the AMA's 22nd Clinical Convention. At this midwinter "summer" session in medicine there will be Three Postgraduate Courses: Fluid and Electrolyte Balance, Diabetes, and Hyperthyroidism in the Elderly Patient • 17 Scientific Sessions • Breakfast Roundtable Conferences • Color Television • and Medical Motion Pictures. The modern, air-conditioned Convention Hall will house hundreds of scientific and industrial exhibits to show you the very latest in equipment, services and drugs.

Plan now to join your colleagues in Miami Beach. Be sure to look for the complete scientific program, plus forms for advance registration and hotel accommodations in the October 21st issue of JAMA.

Physician's Diary

Nothing is enough for the man for whom enough is too little.—Epicurus

Dr. James Cain, Mayo Clinic, is one of three new appointees that President Johnson has named to the Health Advisory Committee that works with the Office of Emergency Planning.

* * *

Dr. Robert H. Ransom, Osseo, was given the community service award presented annually by the administration and the board of trustees of North Memorial Hospital.

* * *

Dr. L. Emmerson Ward, chairman of the Mayo Clinic's Board of Governors, received the University of Illinois' Achievement Award at the University's commencement exercise.

* * *

Dr. Roger A. Johnson succeeded **Dr. Edward J. Engberg** as medical director of the Faribault State Hospital on July 1.

* * *

A distinguished Service Medal was awarded recently to **Dr. Carl M. Eklund,** Minneapolis, by the Secretary of Health, Education, and Welfare, Wilbur J. Cohen.

* * *

Dr. Jerome A. Hilger, St. Paul, has been elected as a vice-president of the American Academy of Facial Plastic and Reconstructive Surgery, Inc.

* * *

Dr. Franz H. Stewart of Miami has been appointed Editor of the Journal of the Florida Medical Association.

* * *

Appointments of ten new staff physicians, two associate consultants and two chief resident associates have been announced by the Mayo Clinic. The ten new staff physicians are: **Drs. Mark Cloutier** and **William Segar,** pediatrics; **John Merideth** and **Richard Van Dellen,** internal medicine; **Robert Garrison,** anesthesiology, **Keith Kelly,** general surgery and surgical research; **Robert Ryan,** endocrine research; **Richard Bryan,** orthopedic surgery; **Manfred Muenter,** neurology and **John Washington II,** microbiology. The two new associate consultants are **Dr. Andrew Lewis,** cardiology and **Dr. Eugene Turner,** pediatrics. The two chief resident associates are **Dr. Arthur Snyder,** general surgery and **Dr. Rafael Cohen,** chief resident in surgery assigned to Rochester State Hospital.

* * *

Gary Falk, Clarkfield, a senior at the University of Minnesota Medical School worked with **Dr. L. A. Syverson** for a month under a program sponsored by the Academy of General Practice established to give students first hand experience in general medical practice.

* * *

Dr. Earl Elkins, a senior consultant in Mayo Clinic's section of physical medicine and rehabilitation, has been named Minnesota's Physician of the Year for the second consecutive year by the Governor's Commission on Employment of Handicapped Persons.

* * *

Mayo Clinic obstetrician and gynecologist, **Dr. E. A. Banner,** has been elected president of the Continental Gynecologic Society at a meeting in Tampa, Florida.

* * *

Two urologists, **Drs. Joseph N. Aquilina** and **Charles H. Brady, Jr.,** joined the Mankato Clinic in July.

* * *

New Locations: Dr. John Marshall has opened up a practice in Pine Island. . . . **Dr. Harold C. Halvorson** has joined the staff of the Albert Lea Clinic. . . . **Dr. L. C. Strough** has joined the Worthington Clinic. . . . **Dr. T. P. Rohrer** who has practiced general medicine in Waseca for the past eight years, is leaving Waseca to further his studies at the University of Cincinnati Medical School. . . . **Dr. David Haldorson** of Duluth has joined the Warren Clinic. . . . **Dr. Fred Martin** has joined the Clearwater Clinic in Bagley. . . . **Dr. John Schotzko** has joined the Blue Earth Medical Center. . . . **Dr. David M. Armin** has joined the staff of the Community Health Center in Two Harbors and **Dr. Robert Nordberg** has joined the medical staff of the Broadway Clinic in Little Falls.

(Continued from page 1477)

PART TIME G.P. OR INTERNIST, 10 to 35 hours a week, examining predominently executive and professional personnel in a downtown Minneapolis medical building. Schedule quite adaptable, even on short notice. $15 per hour plus volume bonus. Write MINNESOTA MEDICINE—417, 375 Jackson, St. Paul, Minnesota 55101.

WANTED: GENERAL PRACTITIONERS, anesthesiologist, Urologist, Obstetrician, Orthopedist, & Pediatrician needed in growing community of 15,000. Service area 25,000. Present 83 bed general hospital. New 100+ bed automated hospital to be completed within 2 years. City has excellent industry, school system, and recreational activities. 45 minutes from Madison or Milwaukee. Future unusually promising. For more information contact: Administrator, Watertown Memorial Hospital, Watertown, Wis.

PUBLIC HEALTH PHYSICIAN—Positions available in local health departments for medical doctors with medical experience and training in public health. Salary range $20,000 to $25,000. Contact Mr. Roy Manty, Chief, Division of Local Health Administration, Department of Public Health, 3500 North Logan, Lansing, Michigan 48914. An equal opportunity employer.

PEDIATRICIAN and OPHTHALMOLOGIST wanted to join multi-specialty group in Virginia, Minnesota. Heart of the expanding taconite industry. Salary arrangement to start with, early shareholder status. Call or write Charles A. Tietz, M.D., Lenont-Peterson Clinic, Ltd., Virginia 55792, or call collect, area code 218, 741-4292.

EXPERIENCED GENERAL PRACTITIONER wants location in Twin Cities single or *small* group. Write MINNESOTA MEDICINE—368, 375 Jackson St., St. Paul 55101.

What's New?

New simple skin test for Histoplasmosis.

Lederle Laboratories recently announced the availability of a simple disposable skin test for the detection of Histoplasmosis infection. The test is performed using a stainless steel disc with four tines and the device is disposable. The advantages of the Histoplasmin Tine Test include convenience, ease of handling and low cost. The test is almost painless and its use in the physician's office should prove of great value.

Isuprel (Winthrop) is reported by a group of investigators to increase cardiac output at both normal pH and in the acidotic state. Reference, *Surgery* (63:181, 1968).

Schering Corporation reports to the profession that Tinactin (tolnaftate) is now available in a powder form. This new powder is a prescription drug and is available for those patients who may use it as effective method of maintaining the remission of fungous infection. The powder is packaged in a 45 gm. plastic container. Schering Corporation reports no side effects or contraindications.

Office laboratory procedures are said to be simplified with a new blood chemistry testing system developed by the **Dow Chemical Company,** Midland, Michigan. Advance information indicates that the system is applicable to hemoglobin, glucose, cholesterol, urea nitrogen, total bilirubin and uric acid, and testing time ranges from five to twenty minutes. The Dow Company invites requests for further information.

Minnesota Medicine at a Glance

Sulfonylurea Therapy—*Balodimos & Marble* Page 1341.

By evaluating diabetic angiopathy through the incidence of cardio- and peripheral-vascular disease, diabetic nephropathy and retinopathy, these authors were unable to identify any difference in the frequency of vascular disease between the use of insulin and that of an oral sulfonylurea drug.

Whipple's Disease—*Bornstein et al.* Page 1345.

Whipple's disease, previously considered uniformly fatal, now appears to be potentially curable with appropriate antibiotic therapy. The classic description of this condition represents the more advanced and terminal stages of the disease. A review of the reported cases suggests that the diagnosis could be suspected earlier on the basis of certain symptoms and findings.

A patient is presented in whom the clinical diagnosis of lymphoma had previously been made, but who failed to respond to cyclophosphamide therapy. Following a change in his clinical manifestations, the diagnosis of Whipple's disease was established. Of the earlier manifestations of this disease, nonspecific arthropathy may precede all others by several years; constipation may be the first or only gastrointestinal symptom; and hyperpigmentation of the skin may serve as an important clue to the early diagnosis of Whipple's disease. The diagnosis can be established by lymph node or small bowel biopsy when stained with periodic acid Schiff's reagent.

Esophageal Resection—*Peterson et al.* Page 1351.

Thirty-six cases of esophageal resection are present. Thirty were for malignancy, and of these seven are free of disease, four for over five years. Reconstruction is accomplished by transplanting the stomach up into the chest and anastomosing it to the remaining esophagus.

Clinical Reviews

A program of lectures and discussions on problems of general interest in medicine and surgery will be presented at the Mayo Clinic and Mayo Foundation, Rochester, Minnesota. Identical sessions are offered on October 28, 29 and 30 and November 11, 12 and 13.

This program is acceptable for credit by the American Academy of General Practice and the College of General Practice of Canada. The registration fee for this program is $20.

The number of physicians who can be accommodated is necessarily limited. For this reason identical programs will be offered two successive weeks. The program will be presented first on October 28, 29 and 30 and repeated on November 11, 12 and 13. Those wishing to attend should communicate with M. G. Brataas, Mayo Clinic, Rochester, Minnesota 55901, indicating which session they would prefer to attend.

NOVEMBER, 1963

Special Issue

Rheinische Friedrich Wilhelm Universitat of Bonn, West Germany

An antibiotic should work well in either acid or alkaline urine.

It isn't always necessary to adjust urinary pH in treating G.U. infections.

Not when the causative organism is a strain sensitive to DECLOMYCIN® Demethylchlortetracycline, as is often the case.

DECLOMYCIN remains stable and active in either acid or alkaline urine. So there's no need to acidify the urine to keep the antibiotic at work.

Why match the urine to the antibiotic...when you can match the antibiotic to the urine...by prescribing DECLOMYCIN. A b.i.d. dosage makes therapy convenient for your patient.

Effectiveness: DECLOMYCIN Demethylchlortetracycline should be equally or more effective therapeutically than other tetracyclines in infections caused by organisms sensitive to the tetracyclines.

Contraindication: History of hypersensitivity to demethylchlortetracycline.

Warning: In renal impairment, usual doses may lead to excessive accumulation and liver toxicity. Under such conditions, lower than usual doses are indicated, and, if therapy is prolonged, serum level determinations may be advisable. A photodynamic reaction to natural or artificial sunlight has been observed. Small amounts of drug and short exposure may produce an exaggerated sunburn reaction which may range from erythema to severe skin manifestations. In a smaller proportion, photoallergic reactions have been reported. Patients should avoid direct exposure to sunlight and discontinue drug at the first evidence of skin discomfort. Necessary subsequent courses of treatment with tetracyclines should be carefully observed.

Precautions: Overgrowth of nonsusceptible organisms may occur. Constant observation is essential. If new infections appear, appropriate measures should be taken. In infants, increased intracranial pressure with bulging fontanels has been observed. All signs and symptoms have disappeared rapidly upon cessation of treatment.

Side Effects: Gastrointestinal system – anorexia, nausea, vomiting, diarrhea, stomatitis, glossitis, enterocolitis, pruritus ani. Skin – maculopapular and erythematous rashes; a rare case of exfoliative dermatitis has been reported. Photosensitivity; onycholysis and discoloration of the nails (rare). Kidney – rise in BUN, apparently dose-related. Transient increase in urinary output, sometimes accompanied by thirst (rare). Hypersensitivity reactions–urticaria, angioneurotic edema, anaphylaxis. Teeth – dental staining (yellow-brown) in children of mothers given this drug during the latter half of pregnancy, and in children given the drug during the neonatal period, infancy and early childhood. Enamel hypoplasia has been seen in a few children. If adverse reaction or idiosyncrasy occurs, discontinue medication and institute appropriate therapy. Demethylchlortetracycline may form a stable calcium complex in any bone-forming tissue with no serious harmful effects reported thus far in humans.

Average Adult Daily Dosage: 150 mg q.i.d. or 300 mg b.i.d. Should be given 1 hour before or 2 hours after meals, since absorption is impaired by the concomitant administration of high calcium content drugs, foods and some dairy products. Treatment of streptococcal infections should continue for 10 days, even though symptoms have subsided.

Capsules: 150 mg; Tablets: film coated – 300 mg, 150 mg and 75 mg of demethylchlortetracycline HCl.

You can be there with NCME TV!

The first nationwide medical television service, NCME—The Network for Continuing Medical Education—brings you visually the important achievements of leading medical authorities. By means of closed-circuit television, this independent network provides your hospital or medical school with a complete videotape service that helps shorten the gap between new medical knowledge and its availability for clinical or teaching purposes.

NCME
The Network for Continuing Medical Education

NCME TV Offers These Practical Benefits:

☐ Every two weeks a new 60-minute videotape dealing with three separate medical subjects is sent to participating institutions.

☐ Content and format of NCME telecasts fulfill criteria for postgraduate medical education, permitting American Academy of General Practice course credits under specified conditions.

☐ To help your institution make effective use of closed-circuit television, NCME offers a wide range of services and utilization aids, including: Technical consultation in setting up a closed-circuit system; advance program information on the contents of each telecast; display units to help publicize programs; expense-paid seminars to improve utilization of medical television.

☐ NCME programs are brief and may be shown as often as desired; you can view the telecasts at times that are most convenient, without disrupting your normal schedule.

☐ Frequently NCME makes available published papers related to subjects presented on closed-circuit television.

A recent NCME hospital telecast presented Philip N. Sawyer, M.D., Professor of Surgery and Head of the Vascular Surgical Service at Downstate Medical Center, Brooklyn, N.Y., in a demonstration and evaluation of "Gas Endarterectomy."

In this program, Dr. Sawyer performs the operation on a patient with gross occlusion of the right iliac, femoral and popliteal arteries.

In Dr. Sawyer's view, gas endarterectomy has several advantages over mechanical methods: the operation can be completed faster, causes less damage to the arteries and offers a more successful outcome.

NCME is an independent network supported by Roche Laboratories to increase the use of closed-circuit TV for medical education under direct hospital and school control.

If your hospital or school does not participate in the biweekly NCME program, information on the cost-free service may be obtained by writing to NCME, 342 Madison Avenue New York, N.Y. 10017

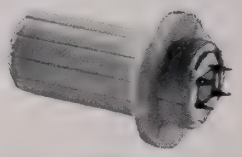
BETTMAN ARCHIVE

Just one tablet at bedtime • Prevents painful night leg cramps • Permits restful sleep

How many of your patients stamp their feet at night and lose sleep because of painful leg cramps? Unless prompted, they usually fail to report this distressing condition and suffer needlessly.

One tablet of QUINAMM at bedtime usually controls distressing night cramps and permits restful sleep with the initial dose.



Prescribing information—Composition: Each white, beveled, compressed tablet contains: Quinine sulfate, 260 mg., Aminophylline, 195 mg. **Indications:** For the prevention and treatment of nocturnal and recumbency leg muscle cramps, including those associated with arthritis, diabetes, varicose veins, thrombophlebitis, arteriosclerosis and static foot deformities. **Contraindications:** QUINAMM is contraindicated in pregnancy because of its quinine content. **Side Effects/Precautions:** Aminophylline may produce intestinal cramps in some instances, and quinine may produce symptoms of cinchonism, such as tinnitus, dizziness, and gastrointestinal disturbance. Discontinue use if ringing in the ears, deafness, skin rash, or visual disturbances occur. **Dosage:** One tablet upon retiring. Where necessary, dosage may be increased to one tablet following the evening meal and one tablet upon retiring. **Supplied:** Bottles of 100 and 500 tablets.

Dilantin®
(diphenylhydantoin)

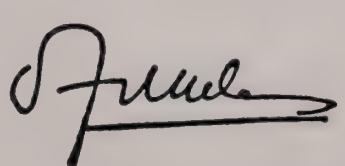
PARKE-DAVIS

In untold thousands of epileptic patients... Dilantin has been, and continues to be, the bedrock of therapy.

DILANTIN is useful in the treatment of grand mal epilepsy and certain other convulsive states. Its use will prevent or greatly reduce the incidence and severity of convulsive seizures in a substantial percentage of epileptic patients, without the hypnotic and narcotizing effects of many anticonvulsant drugs.
PRECAUTIONS: Periodic examination of the blood is advisable. Nystagmus in combination with diplopia and ataxia indicates dosage should be reduced. The possibility of toxic effects during pregnancy has not been explored. ADVERSE REACTIONS: Allergic phenomena such as polyarthropathy, fever, skin eruptions, and acute generalized morbilliform eruptions with or without fever. Rarely, dermatitis goes on to exfoliation with hepatitis, and further dosage is contraindicated. Gingival hypertrophy, hirsutism, and excessive motor activity are occasionally encountered. During initial treatment, side effects may include gastric distress, nausea, weight loss, nervousness, sleeplessness, feeling of unsteadiness. Macrocytosis, megaloblastic anemia, leukopenia, granulocytopenia, thrombocytopenia, pancytopenia, agranulocytosis, and aplastic anemia have been reported. Nystagmus, lymphadenopathy, lupus erythematosus, erythema multiforme (Stevens-Johnson syndrome), and a syndrome resembling infectious mononucleosis with jaundice have occurred.
DILANTIN is supplied in several forms including Kapseals® containing 0.1 Gm. and 0.03 Gm. diphenylhydantoin sodium.
Parke, Davis & Company, Detroit, Michigan 48232

The color combinations of the banded capsules are Parke-Davis trademarks. The orange-banded white capsule identifies Parke-Davis 0.1 Gm. diphenylhydantoin sodium; the pink-banded white capsule 0.03 Gm. diphenylhydantoin sodium.

PARKE-DAVIS 018R67



President's Letter

EARLY IN THIS century, no medical education was complete without post-graduate study on the continent. Doctor Howard B. Sprague, in his foreword to the George E. Fahr Festschrift, calls this "the Grand Tradition, the tradition of solid European training in the magnificent years before World War I." In speaking of Doctor Fahr, Doctor Sprague went on to say, "His is the tradition of the great teachers who brought back to the United States the knowledge and inspiration of the clinical and research giants." Indeed, Doctor Fahr did reminisce about his teachers—Max von Frey and Leube at Würzburg, Einthoven at Leyden, Siegfred Garten at Giessen, Adolph Weber at Bad Nauheim, Ascher at Bern, Volhard at Frankfurt, Krehl at Heidelberg, Romberg and Friedrich von Mueller at Munich, and Rudolph Straehelin at Basel. Common to these teachers and their schools was what Doctor Fahr used to call *"Lernfreiheit"*.

Now, in these pages, our German confreres from the Rheinische Friedrich Wilhelm Universitat, Bonn, West Germany, come to us, and we bid them welcome. Their land has named many stars to the medical firmament—von Bergmann, Paul Ehrlich, August von Wassermann, Robert Koch, Jakob Henle, Rudolph Virchow, Wilhelm Konrad Roentgen, and many more. As Sir William Osler has said, "It is one of our chief glories and one of the unique features of the profession that, no matter where the work is done in the world, if of any value, it is quickly utilized."

This literary visit of our German friends is a fitting example of the universality of medicine, "the only world-wide profession following everywhere the same methods, actuated by the same ambitions, and pursuing the same ends."

May we, in the future, receive similar visits from elsewhere on the globe.

It's almost as if you were there to give an injection of penicillin

V-Cillin K®, Pediatric dependable oral penicillin therapy

Potassium Phenoxymethyl Penicillin

Description: V-Cillin K, the potassium salt of V-Cillin® (phenoxymethyl penicillin, Lilly), combines acid stability with immediate solubility and rapid absorption. Higher, more rapid serum levels are obtained than with equal oral doses of penicillin G.

Indications: Streptococcus, pneumococcus, and gonococcus infections; infections caused by sensitive strains of staphylococci; prophylaxis of streptococcus infections in patients with a history of rheumatic fever; and prevention of bacterial endocarditis after tonsillectomy and tooth extraction in patients with a history of rheumatic fever or congenital heart disease.

Contraindication: Penicillin hypersensitivity.

Warnings: In rare instances, penicillin may cause acute anaphylaxis which may prove fatal unless promptly controlled. This type of reaction appears more frequently in patients with a history of sensitivity reactions to penicillin or with bronchial asthma or other allergies. Resuscitative drugs should be readily available. These include epinephrine and pressor drugs (as well as oxygen for inhalation) for immediate allergic manifestations and antihistamines and corticosteroids for delayed effects.

Precautions: Use cautiously, if at all, in a patient with a strongly positive history of allergy.

In prolonged therapy with penicillin, and particularly with high parenteral dosage schedules, frequent evaluation of the renal and hematopoietic systems is recommended.

In suspected staphylococcus infections, proper laboratory studies (including sensitivity tests) should be performed.

The use of penicillin may be associated with the overgrowth of penicillin-insensitive organisms. In such cases, discontinue administration and take appropriate measures.

Adverse Reactions: Although serious allergic reactions are much less common with oral penicillin than with intramuscular forms, manifestations of penicillin allergy may occur.

Penicillin is a substance of low toxicity, but it possesses a significant index of sensitization. The following hypersensitivity reactions have been reported: skin rashes ranging from maculopapular eruptions to exfoliative dermatitis; urticaria; and reactions resembling serum sickness, including chills, fever, edema, arthralgia, and prostration. Severe and often fatal anaphylaxis has occurred (*see* Warnings). Hemolytic anemia, leukopenia, thrombocytopenia, and nephropathy are rarely observed side-effects and are usually associated with high parenteral dosage.

Administration and Dosage: Usual dosage range, 125 mg. (200,000 units) three times a day to 500 mg. (800,000 units) every four hours. For infants, 50 mg. per Kg. per day divided into three doses.

See package literature for detailed dosage instructions for prophylaxis of streptococcus infections, surgery, gonorrhea, and severe infections.

How Supplied: Tablets V-Cillin K® (Potassium Phenoxymethyl Penicillin Tablets, U.S.P.), 125 mg. (200,000 units), 250 mg. (400,000 units), and 500 mg. (800,000 units).

V-Cillin K® (potassium phenoxymethyl penicillin, Lilly), Pediatric, for Oral Solution, 125 mg. (200,000 units) and 250 mg. (400,000 units) per 5 cc. of solution (approximately one teaspoonful). [042567A] 800198

Surgery of Gastric Carcinoma

PROFESSOR ALFRED GÜTGEMANN, M.D.*
Bonn, West Germany

THREE DECADES AGO (1938) Konjetzny spoke of "The Tragedy of the Stomach Carcinoma Patient." Today these words have the same tragic meaning if one realizes that about 25,000 citizens of the Federal Republic (West Germany) succumb every year to this disease.[27] In men this disease leads the mortality statistics, surpassing bronchial carcinoma and carcinoma of the genitourinary tract; in women it ranks ahead of carcinoma of the genital organs and of the breast.[7]

The history of surgery for gastric carcinoma shows periods of intensive endeavors in the developments of operative techniques followed by periods of resignation with regard to the postoperative prognosis. The doubts are based on the uncertain efficacy of gastric resections and especially of the more radical operative procedures, which carry a high mortality, even though this has been decreased with experience. *Much of the criticism has been directed against the presumably unavoidable and serious postoperative defect syndromes.*

It is a widely held belief that the price for prolongation of life is a so-called psychosomatic *vita minima* signified by agastric dystrophy[35] and by cachexia.

Knowing the history of gastric surgery it would be presumptuous to call present day developments a Renaissance of gastric surgery; still, surgery of the stomach is on the move. This applies to operations for peptic ulcer as well as for gastric carcinoma. In addition to curing the disease itself the operations are more and more designed to maintain the digestive synergism. In the surgery of peptic ulcer disease, for example, this has led to attempts to retain a sufficient gastric remnant, a residual acidity and an orthograde† duodenal passage.

Furthermore, there is apparently a causative potential carcinogenesis relationship in the type of resection and anastomosis for stomach ul-

*From the Department of Surgery, Director; University of Bonn. (Read at the Congress on Metabolism, Bad Mergentheim, October 22-23, 1966.)

†See Test Your Word Score Page 1583.

cers.[11] This was evident in comparing patients with Billroth-II- and Billroth-I-resections, where the incidence of gastric carcinoma in the stomach remnant was 2½ times larger in Billroth-II- than in Billroth-I-resections.[19,20] The incidence of carcinoma in the stomach pouch after Billroth-II-resections for ulcer was one in six, and the average period of latency was 21 years.[20] Achlorhydria and hyperplastic gastritis (transformation gastritis) developing after Billroth-II-resections in the stomach pouch apparently favor the development of a carcinoma.[47,49,71]

Aggressive eradication of the primary cancer, which threatens to involve the entire organism and ultimately kill the patient, is the only promising method of treatment of gastric cancer at this time. The problem of cancer surgery in the stomach is thus quite different from that of ulcer surgery.

The prognosis of surgically-treated stomach cancer depends largely upon the extent of resection. Radical removal must be striven for, since every attempt to retain the organ constitutes a heavy mortgage on cure. Even at operation it is not always possible to confidently determine the extent of the stomach carcinoma. Thus an assessment of the optimal degree of radical management becomes even more difficult. This, however, should not lead us to the conclusion that a curative resection is impossible in every case.

Mortality

The average stomach carcinoma patient dies approximately 5.5 months after the diagnosis has been established. The longest survival time without surgery has been 31 months. The patient who has undergone a resection—including operative mortality—can expect a four-times-longer survival time of 20.5 months.[27]

Subtotal Distal Gastrectomy

Let us consider the example of stomach carcinoma in the distal half, which is the most frequent site. A very impressive increase in five-year survival during the last six decades after an *extended subtotal distal gastrectomy* becomes evident. In three sequential series the absolute five-year survival rises from 7.1% to 16.1% to a present 29.1%.[3] This represents a four-fold increase. Other groups report similar improvements in results.[8,18,34,60,86]

One third of the patients with distal gastrectomy survived five years without recurrence, and further followup shows an increased life expectancy beyond the tenth postoperative year.[78]

Total Gastrectomy

Twenty percent of patients with carcinoma involving the entire stomach, treated in the past by *total gastrectomy* only, survived the fifth postoperative year. A followup of these patients also shows a considerable number of 10-year survivors without signs of recurrence.[24,25,26]

The absolute rate of resection for gastric carcinoma represents a measure of diagnostic reliability: the number of resectable stomach carcinomas divided by the total number of patients hospitalized for stomach carcinoma. The percentages during the three sequential periods in our institution rose for cancer in the distal stomach from 27.5% to 31.4% to 32.7% at the present time. They may be considered almost unchanged. The absolute rate of resection, however, rises to 40.1% and 44.2%,[78] if one includes total gastrectomy, which has become more frequent in recent years, and proximal gastrectomy for carcinoma of the cardia.

Advanced Operative Technique

The majority of patients with gastric carcinoma do not benefit from advanced operative techniques, nor do they show improved cure rates. Since it has not been possible to increase the number of resections by earlier recognition of the disease, our studies have led to two basic conclusions:

1. The development of advanced operative techniques in stomach carcinoma has resulted in great improvements.
2. The diagnostic effectiveness in stomach carcinoma, using clinical symptoms, laboratory findings and information obtained directly from the patient, has remained constant over the years. This disappointing but permissible conclusion is based on the incidence of resections and on the fact that nothing so far indicates a

change in the biological nature or the aggressiveness of gastric carcinoma.

The "early clinical diagnosis" is obviously complicated by the long period of latency in malignant degeneration, the biological viciousness of undifferentiated small cell carcinoma of the stomach, the frequent protean symptomatology, the problems of diagnosis, and the absence of unequivocal hematological and serological findings.[2] It is significant that the average time lapse between the patient's first consultation and the referral to the surgeon has been six months.[76,77] The complaints were too frequently attributed to a harmless gastritis, even after X-ray examination, although gastritis per se is quite rare. The complaints of dyspepsia all too often masked a carcinoma.

X rays

In reviewing previous X rays, it was frequently found that the early signs of carcinoma were either not recognized or were mistaken for gastritis. In spite of persistent dyspepsia some patients were not adequately followed clinically and radiologically, delaying the correct diagnosis. Sometimes the faith in an X-ray picture seems to be unshakeable.* On the contrary, the interpretation of an X-ray film should be influenced by the clinical symptoms. If there is a suspicion of carcinoma, further X-ray examination is called for.[22,40,62]

Surgical Principles In Carcinoma of the Stomach

Conventional Gastrectomy

The conventional gastrectomy for ulcer is confined to the skeletonizing of the lesser and greater curvature. Such a procedure would disregard the histologically recognizable extension of the cancer within the stomach wall.[14,57] Thus in relying upon the gross appearance one might believe that a circumscribed resection has been done within healthy tissue, and one might overlook carcinoma cell clusters in the remaining portions of the stomach which appear grossly to be uninvolved. This applies especially to the lesser curvature where about 85% of all stomach carcinomas appear.[27,45]

The conventional carcinoma resection has been found to be insufficient even when proven regional node metastasis is evident, as clearly shown in the fact that two thirds of the recurrences after subtotal gastrectomy originated on the lesser curvature side of the stomach pouch and one third in the remaining regional lymph nodes.[11,74]

Radical Gastrectomy

The principles of radical gastrectomy for carcinoma include the maintenance of[21] proximal and distal safety margins with resection through microscopically proven healthy tissue. In practice this is done by a stepwise, subtotal resection which includes the entire lesser curvature and sacrifices 80 to 90 percent of the stomach; the lesser and the greater omentum and all lymph nodes up to the coeliac axis should be removed in continuity by "en-bloc-resection" which includes the transection of the four main gastric arteries and removal of the contiguous lymph vessels and lymph nodes.

Types of Gastrectomy

If one includes the so-called cardia carcinoma which, by gross appearance, histology, and mode of extension, represents a carcinoma of the proximal stomach, there are three basic types of gastrectomy for carcinoma which correspond with the site and extension of the tumor: *distal gastrectomy* for carcinoma of the antrum or the lower corpus according to the principles discussed above,[24,25,26] *proximal gastrectomy* for carcinoma of the fornix and the corpus of the stomach including the cardia.[24,25,26] and *total gastrectomy*.[24,25,26]

Indications

The indication for gastrectomy[39,52] is always positive when: the carcinoma involves a major portion of the body of the stomach (especially of the lesser curvature) and it is impossible to maintain a safety margin of 6 cm; a diffusely infiltrating tumor with the histological picture

*"Denn was man schwarz auf weiss besitzt, kann man getrost nach Hause tragen."

What we possess in black and white,
We can in peace and comfort bear away.—J. W. Goethe, Faust.

Editor's Note: These words are spoken by the student to Mephistopheles who is masquerading as Faust. As for the context: Mephistopheles is confounding the student with specious and abstruse *metaphysics*, when what the student wants is definite *knowledge*.

of undifferentiated small cell carcinoma (carcinoma granulomatosum or a carcinoma gelatinosum) is found, since these tumors tend to have intramural extension which is difficult to recognize grossly; the tumor has metastasized beyond the primary lymph node drainage or if a so-called lymph node jump strip exists (however, only if distant metastases—lymphogenous, hematogenous, or intra-cavitary—are not present); the cancer involves the spleen, the left liver lobe, the pancreas, or the transverse colon, but is still resectable by an extended procedure.

Functional Impairment

Extended radical resections lead to functional impairment. Besides reconstitution of continuity of the digestive tract, the re-creation of a sufficient food reservoir is of particular importance.

Much concern over the advisability of radical gastrectomy and its sequelae has been voiced. At the same time modern cancer surgery has progressed far through a better understanding of the postoperative pathophysiology after radical gastrectomy and by the development of substitutional techniques.

Deficiency Syndrome

In the past an underestimation of the possibilities of radical cancer surgery, together with the observation that elderly patients show a markedly decreased adaptation to the newly created metabolic conditions, have led to a certain fatalism. This deficiency syndrome is invariably caused by lack of a nutritional reservoir leading to inanition, or to an accelerated upper intestinal passage, with incomplete utilization of the ingested food, which then leads to a malabsorption syndrome and to the so-called agastric dystrophy. Thus, all operative techniques which include the anastomosis of a too-small gastric remnant with the jejunum or the esophagoduodenostomy and esophagojejunostomy are functionally inadequate and hence unsatisfactory.

Physiologic Reservoir

In total gastrectomy or in all cases where the stomach pouch is smaller than 25 percent, creation of a new reservoir with sufficient capacity is required.[21,56,69] It is equally important to maintain the orthograde duodenal passage in order to insure a coordinated course of the digestive mechanisms located in the duodenum. We prefer the interposition of a jejunal loop between esophagus and duodenum of at least 25 to 30 cm in length after subtotal and total gastrectomies, either between the stomach pouch and duodenum or between the esophagus and the duodenum.[21,41]

Results

Our experience includes 136 such jejunal interposition operations: 120 after total, nine after proximal, and seven after distal gastrectomy.[3,27,78] The use of an isolated colonic segment[33] appears inadvisable, especially since the rationale for this procedure is based solely on animal experiments.

Metabolic Tests

Detailed metabolic tests performed on our patients prove that the interposed small intestinal segment, which functions as a stomach, fulfills its physiological tasks.[4,5,10] Besides the design and function of such operation, one has to take into account the objective and subjective symptoms in patients who undergo this procedure.[58,81,82] After a few weeks the fluoroscopy and cinematography show a good adaptation of the interposed small bowel loop to its new task: there is an elongation and dilatation of the loop which lies close to the left diaphragm and mimicks the position and shape of the stomach. This adapted small bowel loop serves as a reservoir for ingested food and as a mixing chamber as well.

Physiologic Propulsion

There is a physiological rhythm of food propulsion into the duodenum and into the upper small bowel which is an important prerequisite for an orderly course of digestive mechanisms. We have never seen in our patients any subjective or objective evidence of jejuno-esophageal reflux after small bowel interposition. Neither has there been any reflux esophagitis. We have, however, seen very bothersome reflux esophagitis on occasion in patients where the distal stomach stump was anastomosed to the esophagus.[58,73,79] Thus one might almost speak of a stomach-like transformation of the jejunal loop, which results in a sufficient ca-

pacity of the pseudo-stomach to permit the patient to resume his accustomed pattern of eating.

We know that a stomach which is too small leads to decreased food intake, culminating in apprehension and consequent starvation because the patient fears the symptoms which result from adequate food intake. By providing the patient with a stomach reservoir he can be adequately nourished; his entire nutritional and metabolic situation improves, and his attitude toward his disease and the newly gained life span improves progressively.

Digestive Function

Hydrolysis of the food proteins starts immediately in the interposed loop of small intestine through the action of regurgitated tryptic pancreatic proteases as well as the proteases produced by the bowel itself. Enzymatic protein cleavage and resorption of amino acids was checked by determining the level of amino acids in the serum during the fasting state and after a standard cottage cheese meal. Although the peak of amino-acid absorption appeared earlier and was found to be higher than normal, the total amount absorbed was found to be quite sufficient for all amino acids, including those which the body cannot synthesize. Total serum proteins and the electrophoretic pattern of serum proteins were normal after total gastrectomy and interposition of a small bowel loop. Immunoelectrophoresis showed neither dysproteinemia nor paraproteinemia indicative of nutritional or absorptive disturbances.[4,5,10]

Acidification

Besides the maintenance of an orthograde duodenal passage it is important to acidify the ingested food. This results in a pancreatic secretion rich in water and bicarbonates and poor in enzymes. One can thus avoid the precipitate proteolysis which occurs when pancreatic juice, rich in enzymes and poor in water, acts on the chyme and causes a speeded-up intestinal passage due to osmotic action.[33] Also the ionization of iron and calcium, important for their absorption, calls for acidity.[50,51] At last the ingested acid has a favorable effect on the microecology of the intestines.

Follow-Up

Substitution Therapy

Although the creation of a stomach substitute with an orthograde duodenal passage and fulfillment of physiological requirements induces favorable postoperative conditions, a long-term thorough followup is indispensable. Attention has to be paid to a sufficient intake of hydrochloric acid at meals and of bivalent iron, calcium, folic acid and vitamin B_{12}. A life-long substitution of vitamin B_{12} is absolutely necessary because of the removal of the gastric mucosa which forms the intrinsic factor.[65] One should also keep in mind the possibility of an exhaustion of the iron and calcium stores in the organism with consequent iron deficiency anemia or osteoporosis. These conditions can be either avoided or treated by an increased oral or parenteral substitution.

Feeling of Well-being

The value of gastric replacement procedures is borne out by the results in patients who undergo this procedure. The body weight remains close to normal. Freedom from symptoms and a general feeling of well-being leads in many cases to the resumption of work. After a period of adaptation of from three to 12 months, and in the absence of recurrence, any regimentation of food intake usually becomes unnecessary. Even in the absence of the stomach a sensation of hunger occurs at the usual times. It is of physiological as well as of psychological interest that one often finds in these patients a craving for certain foods which may not be easily digestible. For our patients we recommend a full diet rich in proteins, vitamins and minerals, and we discourage any type of special diets which in the long run are always starvation diets.

Conclusions

The application of the general principles of cancer surgery to stomach cancer results in more radical procedures and a better prognosis.

The dangers of starvation and of agastric dystrophy are overcome by maintenance of an orthograde duodenal passage and the preservation or creation of a sufficient food reservoir. This type of cancer surgery can benefit a larger

number of patients by increasing the number of curative resections.

Also beneficial is more extensive use of all modern diagnostic procedures, including X-ray examination, gastrocamera, gastroscopy, blind or open-mucosal biopsy in the stomach, cytologic study of gastric washings, and finally, increased use of exploratory laparotomy aided by histological examination.

Dyspeptic complaints are not characteristic and may herald an early stomach carcinoma. Only careful diagnosis and observation of patients with symptoms suspicious of gastric carcinoma will lead to more frequent recognition of the disease.

Finally, it is an important, albeit difficult, task to guide and follow a patient with gastrectomy after his hospital discharge. The incurable patient needs mostly psychological support, whereas the patient with a curative resection needs wholesome, nutritious food and substitution therapy as indicated by periodic laboratory determinations.

When a surgeon has occasion to resect a gastric carcinoma which was limited in size and had not metastasized beyond the area of resection, most of the praise should go not to him but to the physician who recognized the carcinoma early and refused to be misled by negative or questionable findings.

Throughout the past, recurrent periods of therapeutic resignation have been the main obstacle of stomach-carcinoma surgery. Anschütz said in 1914 at the 43rd Convention of the German Society for Surgery in Berlin: "I am glad to see more swing today in surgery of stomach carcinoma. For some time courage had waned. There were frustrating results. I believe that today's fine presentation of Herr Kuttner will animate us more and give us more confidence in resections. I suppose everyone will feel as I do when one follows the long-term results: I was surprised how many good results finally emerge."

From today's vantage point one should add that we now can recognize carcinoma earlier, that we can excise it with a better chance of success, and that in spite of extended resections we can make the postoperative existence worth living. Our experience of more than 15 years has shown that it is possible to compensate for the loss of the entire stomach by reconstructive substitution. Thus, in surgery of gastric carcinoma we can also observe the basic rule of all physicians, namely to heal more than to damage. The past reservations against the radical removal of gastric carcinoma should be abandoned.

He must have had a magnificent build before his stomach went in for a career of its own.—Margaret Halsey

Fibrinolytic Activity after Surgery*

D. WUELFING, M.D.
K. P. BRANDAU, M.D.
Bonn, West Germany

WHILE STUDYING the relations between surgical operations and fibrinolysis most examiners determined the fibrinolytic activity only during the first twenty-four postoperative hours. The main reason to examine the increase of fibrinolysis is to evaluate the fibrinolytic hemorrhages. Condurso[7] examined 30 patients immediately after surgery and found 3.3% complete lysis, but others[4,6,14,18,21] who examined their patients on the first postoperative day did not find increased fibrinolysis.

Thies[27] examined the fibrinolytic potential not only preoperatively and on the day of surgery but also on the first, third, fifth and eighth postoperative days. He determined the profibrinolysis-, antifibrinolysis- and fibrinolysis times[15] and the Heat-Fibrin[22] and found slightly increased fibrinolysis in seven out of 46 patients with minor or major surgical operations as well as in some accidents. He made his determinations four times: on the day of surgery and once each on the first, fifth and eighth postoperative days. No lysis was observed in the other 39 patients. The fibrinolysis content was always below 3%. The least fibrinolytic activity was observed on the third postoperative day (mean of evaluation of 32 patients). The author concluded that there is rarely an elevation of the fibrinolysis content postoperatively on the days which he used for evaluation. Similar results were reported by Tsitousis et al.[8] who examined the fibrinolytic action in 13 patients preoperatively and on the first, third and seventh postoperative days after major surgery. Using the lysis of a standard fibrin clot as the method, no spontaneous fibrinolytic activity could be observed. It can be said therefore that an increased fibrinolysis during the first postoperative week is a rare thing according to the results of the above-named authors. Up to now it has not been possible to demonstrate any definite changes in the postoperative fibrinolytic activity.

We intend now to observe the action of the postoperative fibrinolysis over an extended

*See editorial page 1579.

time and, in addition, to determine if there is possibly a decreased fibrinolytic activity. This problem has clinical interest since delayed fibrinolysis has been regarded by Stamm[25] as one factor in thrombogenesis.

Clinical-Experimental Examinations

The fibrinolysis tests were done on patients with thoracic surgery, because the lungs belong to the group of organs with a high content of tissue activator, as has been reported previously by different authors.[1,2,24,25,26] Zaman[29] found a surplus of plasminogen activator up to 20 hours postoperatively after lung resections, apparently originating from injured lung tissue. In addition there is a possibility that the lung may activate fibrinolysis by change to a more acid p-H (for instance in respiratory acidosis). Nielsson[19] and Schultz et al.[23] found increased fibrinolysis concomitant with decreased oxygen saturation of the blood. Some authors [8,13,17] also found an increase of fibrinolytic activity during metabolic acidosis.

Heart operations could induce activation of the fibrinolytic system, particularly when extracorporeal circulation is used for a long time or with the stress of replacement of blood or contact of the blood with artificial surfaces such as the heart-lung machine.

It therefore appears that heart and lung operations very likely may cause changes in the fibrinolytic system due to trauma during surgery and postoperatively due to disturbances of respiration and circulation.

The Problem

The following questions shall be examined:

1. Are there definite changes of the fibrinolytic activity during the postoperative course?
2. Is the extent of the changes dependent upon the kind of surgery? Particularly, is there a difference between thoracic and extrathoracic operations?
3. Are the observed changes of the fibrinolysis dependent on complications of respiration and circulation?
4. At what time after surgery are the changes of fibrinolytic activity most pronounced?

Type of Operations

The examinations were done on 38 thoracic operations. Controls were nine operations outside the chest.

Thoracic Operations

Type of Operation	Number
Lung	15
Heart with extracorporeal circulation	10
Heart in normal general anesthesia	10
Heart in hypothermia	3

Control Operations

Type of Operation	Number
Splenectomies	3
Laparotomies	2
Kidney	1
Thyroid	1

Method

The fibrinolytic activity was determined with the Euglobulin-Lysis-Time.[11] This method is preferable because of an easy technique, rapidity[5], a short observation time (two-to-four hours) and its sensitivity.[25] Samana and Yver[20] called the method the examination of choice in thoracic surgery because of the short duration of the test, the good correlation of its results with those of the thromboelastogram, and its ability to detect increases as well as decreases of fibrinolytic activity.

Euglobulin-Lysis-Time[11]

Principle

Precipitation of the Euglobulins with acid in citrate plasma causes the Albumin-Antiplasmins to remain in solution while all other fibrinolysis factors precipitate together with the Euglobulins. The Euglobulins are separated with centrifugation and removed, and a Euglobulin solution is made. This solution contains fibrinogen and clotting factors and can therefore be clotted with the use of thrombin. The time of the complete solution of this clot is the measure of the Euglobulin fibrinolysis. It represents the action of the present plasmin without the interference of the Albumin-Antiplasmins.

Normal Values of the Euglobulin-Lysis-Time

According to Kaulla and Schultz[11] the normal value of the Euglobulin-Lysis-Time

is between 120 and 240 minutes, or even a little longer. Less than 120 minutes is considered abnormal, representing increased fibrinolysis. Values of 50 minutes represent a marked acceleration of fibrinolytic activity; values of seven minutes indicate immediate danger of hemorrhage. Stamm[25] found that the lysis of fibrin with the Euglobulin fraction of normal plasma was usually completed in 180 minutes; values between 120 to 240 minutes were regarded as within physiologic limits.

In order to get a normal value for our method we determined the Euglobulin-Lysis-Time in 20 healthy persons (physicians, nurses, students, etc.). The values appear in the Table. A lysis time of 126 minutes was our mean value, with variations between 250 and 65 minutes. Nine of these lysis times were below the 120 minutes which by other authors were regarded as the lower limit. There were nine females and 11 males in this group. Age was between 20-30 years. The blood was drawn in the laboratory and the fibrinolysis determinations were done immediately in order to avoid loss of activity by storage of the specimen. There was a striking difference between the mean values in the female and male groups: the women had an average of 102 minutes, the men an average of 142 minutes. We do not have an explanation for this difference.

Results

Frequency of the Postoperative Determinations

The determination of the fibrinolytic activity was done during a two-week postoperative period in the first 10 patients with thoracic surgery and in the first three control cases. All other examinations were done during the third week after surgery. The examinations were done daily during the first week, every other day during the second week and twice during the third week. Precautions were taken to draw the blood without injury to the tissues in an effort to prevent a liberation of tissue activators of the fibrinolysis by using large blood pressure cuffs and large bore needles with polished lumen. Only siliconized syringes and canulas were used. A double fibrinolysis determination was done immediately and only occasionally was there a delay up to a maximum of 30 minutes.

The fibrinolytic activity after surgery was determined on 47 patients. A total of 452 determinations were made but only 250 were used because in these the dissolution of the fibrin clot could be followed to the terminal point. The results of our research are based on the evaluation of these 250 determinations.

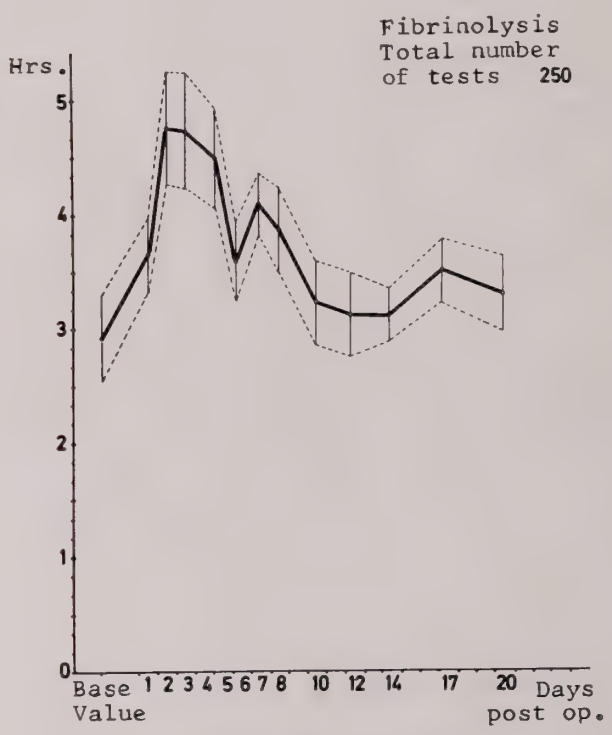
The Mean Value

The mean value preoperatively in 13 patients was 175 minutes. Four of these patients showed a slight increase of fibrinolytic activity (100, 55, 110 and 65 minutes).

Absence of Correlation

None of the operated patients showed a postoperative increased fibrinolysis of clinical importance. Fibrinolysis was not increased (under 120 minutes) in 32 patients. In 15 patients (26 times in 250 examinations) there was a slight increase of fibrinolytic activity with lysis times under 120 minutes. There was no lysis time under 50 minutes. No particular age group was more involved than others. Sex did not make any difference; there were nine male and six female patients in this group. There was no relation to the amount of blood replacement the patients had received: some had received up to five times 250 ml, some less (up to 300 ml), and some did not have any blood transfusions at all. Also there was no correlation between postsurgical complications and increased fibrinolysis.

TABLE



Normal Values of Euglobulin-Lysis-Time in 20 Normal Persons

No.	Sex	Lysis-Time minutes	No.	Sex	Lysis-Time minutes
1	male	135	11	male	250
2	male	135	12	fem.	95
3	fem.	65	13	fem.	120
4	fem.	80	14	fem.	110
5	male	155	15	fem.	70
6	fem.	75	16	male	70
7	male	125	17	male	200
8	fem.	170	18	male	105
9	fem.	135	19	male	115
10	male	200	20	male	120

No observation of a shortened lysis time was observed on any certain postoperative day or with any certain operation.

Postoperative Correlation

While the occasionally observed increased fibrinolytic activity appeared to be not characteristic, we found while evaluating the 250 single tests an obvious *decrease* of fibrinolytic activity (longer Euglobulin-Lysis-Time) during the first postoperative week, maximal between the second and the fourth postoperative days. The fibrinolytic activity remained decreased during the further postoperative course and returned only slowly to the starting values. Even three weeks postoperatively no normalization of the lysis was observed (Figure).

Figure

Discussion

Our starting value of 175 minutes Euglobulin-Lysis-Time correlates with the time reported by Stamm.[25] Slight preoperative increases of fibrinolysis have been observed before by other authors.[4,12] We found, as Thies[27] did, higher fibrinolysis potentials before than after surgery. The preoperative starting value was higher than the postoperative values up to three weeks postoperatively. Thies believed that psychic stress (fear of the operation) and preoperative hunger were responsible for this phenomenon.

The rarity of increased fibrinolysis during the postoperative course reported by Halse,[9] Thies[27] and Tsitousis[28] was confirmed up to three weeks postoperatively in our patients: there was no case of clinically significant increased fibrinolysis. The occasionally observed slight increase in fibrinolysis appeared to be unrelated to age and sex of the patient and unrelated to the kind of surgery. Thies came to the same conclusions. One may question if the observed increases in activity were just normal variations of the physiological fibrinolysis since similar values were found in healthy controls.

In the literature available to us we do not find any reports about an obvious decrease of the fibrinolytic activity during the first three postoperative weeks. The observed significant loss of activity on the second, third and fourth postoperative days is paralleled by the observation of Thies[27] that the smallest increase of fibrinolytic activity was seen on the third and fourth postoperative days in his 32 patients. He observed on these days the lowest profibrinolysis content, a normal antifibrinolysis content, an increase of the Heat-Fibrin and a decrease of the lysis of the fibrin clot, using the test tube method[15] with bovine fibrin. Thies[27] suspects a relation between the low tendency of lysis and the increased clotting tendency which has been shown by Markgraf and Hinrichs[17] to be present on the third and fourth postoperative days.

Conclusions

A decrease of the fibrinolytic activity of an obvious degree is noted during the postoperative time.

The amount of change is not dependent on the kind of surgery. There is no measurable difference of the fibrinolysis between intra- and extrathoracic operations.

We cannot report about a connection between postoperative complications and fibrinolytic activity because we did not encounter any serious complications with our patients.

The decrease of the fibrinolytic activity is particularly present during the first postoperative week. The greatest loss of activity is noted between the second and fourth postoperative days. A return of the Euglobulin-Lysis-Time to normal value occurred after the end of the third postoperative week.

A Family Doctor's Philosophy

It would seem logical, indeed, for a doctor to adopt a material outlook on life, since his business is the care and cure of bodies. I believe that all young doctors experience such a period in their growth. But as one grows older, the fierce denials fall away, and one begins to see that science needs spiritual guidance if it is to aid mankind on any road but a long fool's errand to the grave.

Being a creature of science disposes me more often than not to range myself under the banner of science, only to find that it will not do. As soon as I consider the wonders of the body, the miracles of the mind are forced on my attention; and if I rely on the mind, my hands reach for the instruments, since I have proved to myself, over and over, that they have their own special kind of wonders to perform.

How is it possible to separate the two? How can anyone say to me, "Faith or the knife, which will you have?" To him I answer that I will not choose. Too many times in my life I have been reminded that they are indissoluble, and no book on the subject, no ambitious partisan can make me change my mind. I choose both: faith in God and faith in man.*

It's the Law

Primer of Parliamentary Procedure

"American Parliamentary Law is built upon the principle that rights must be respected: rights of the majority, of the minority, of individuals, of absentees, and the rights of all these together."*

"Primer of Parliamentary Procedure"† is written to present physicians with the fundamental principles of organized group action.

The Main Motion

Effective group action depends upon the introduction of new business in the form of a motion, a resolution or a committee report which initiates action. Such a matter may be brought before a properly organized meeting in one of several forms. A member may rise, be recognized by the chairman and state his views. Any other member who concurs may second the action. Then, when made in the proper form, seconded, and stated in full by the chairman the *main motion* is ready for consideration by the group. The fact that a motion has been made and seconded does not put it before the group, as the chairman alone can do this. The chair must either rule the matter out of order or state the motion so that the assembly may understand what is before it for consideration and action. At this point, and at this point only, can debate on the matter begin.

Immediately following the motion and the second, and before the motion is stated by the chair, members may suggest modifications of the motion, and the mover, without consent of the seconder, may make changes in the motion or even withdraw his motion completely. However, once stated by the chair, the motion must be disposed of by the assembly in a proper manner.

Having obtained a proper motion and second, the chairman simply states, "It is moved and seconded that we (stating the motion). Is there any discussion?"

Discussion or debate is now open to any member after recognition by the chair. Recognition in large assemblies requires the member to rise and address the presiding officer by his title, "Mr. President," or "Mr. Chairman" or "Mr. Moderator." Having been recognized by the chair, the member then gives his name and proceeds. In less formal groups, where all the members are known to each other, this identification is unnecessary and the chair may merely indicate recognition by facing or naming the member.

After debate is completed the chair puts the question to vote by saying, "The vote is on the motion that we (stating the motion). Those in favor of the motion say 'Aye;' those opposed say 'No.'"

During the debate or discussion the *main motion* may be modified, in one or several ways, and such alterations will be discussed next month.

Summary

1. A motion must be presented in proper form.
2. It must be seconded.
3. The entire motion must be stated by the chair before discussion or debate begins.
4. There can be only one *main motion* before the society at any one time.

Etiology of Consciousness Disturbances in Surgery

C. KAUFER, M.D.*
Bonn, West Germany

SEVERE PHYSICAL ILLNESSES are often accompanied by psychic disturbances which merit special interest in surgery because of their frequency and grave prognosis. As symptoms they are of clinical value because they alert us to a general illness in the course of a surgical disease.[4] In surgery, disturbances of the mind are usually symptomatic psychoses and must be regarded as one of the symptoms of a known entity, though they are not necessarily an expression of the basic illness.

The most frequent and most impressive clinical symptom is a disturbance of the waking state. At times certain psychic derangements associated with an intellectual or emotional defect are manifested. A chronic loss of efficiency with personality changes is more rare. These aberrations may be reversible or irreversible; they may end with permanent defects, physiologic decerebration,† or even death. The psychic appearance is not necessarily determined by the nature of the underlying disease. For example, it is usually impossible to determine from the pathological symptomatology the exact type of noxious provocation,[1] since different physical illnesses may lead to similar psychic disturbances. The multiplicity of basic physical illnesses is in sharp contrast with the uniformity of psychic symptomatology.

Personal Investigations

Within a period of 10 months we have observed and analyzed 100 cases of serious derangements of consciousness at the Department of Surgery, University Hospitals, Bonn. However, this investigation is neither complete nor representative. One reason is that mild psychic alterations are easily overlooked in the routine of daily clinical work.[17,18] With increasing experience, however, we were able to properly evaluate certain symptoms which usually escape the uninitiated observer, and we began to recognize them as prodroma of mental disturbances.

*From the Department of Surgery, University Hospital, Bonn. Director: Professor A. Gütgemann, M.D.
†See Test Your Word Score Page 1583.

On the other hand, this investigation does not take into account cases of simple brain damage due to concussion or contusion; cases usually found in the accident wards, and of only minimal interest in the investigation of post-surgical mental derangements.

This account gives a general survey of the most frequent causes of mental disturbances in surgical patients (Table 1). Our patients underwent repeated clinical and psychopathological examinations. A number of standard laboratory chemical examinations were also made, and the particular phases of mental disease were repeatedly checked by brain-wave tracings. The neuropathological findings of those patients who died were available for comparison with the clinical course and proved to be quite valuable.

Somatic Causes of Symptomatic Psychoses

Our patient material permits subdivision with regard to causative factors, which proved to be illustrative and easily understood (Figure 1). In many cases of deranged consciousness it is impossible to pinpoint the somatic cause; in other cases a number of causative factors concur. For example, the question might arise whether a disturbed consciousness is caused by hemorrhagic shock following a ruptured spleen, by a simultaneous respiratory dysfunction due to aspiration, or by traumatic brain damage. Such a case exemplifies the possible interaction of different physical mechanisms. The multiple origins of disturbed consciousness, as described by Bleuler, have never failed to appear in our observations. However, we usually list the prevalent causative factor and elect to list multiple causative factors only if a retrospective analysis does not permit an exact pathogenetic classification.

Cerebral Disease

We have subdivided the organic diseases into *cerebral* and *extra-cerebral* disturbances (Table 2). These are mainly traumatic brain lesions either direct or indirect, or cerebral lesions caused by brain edema. The organic brain lesions are less frequent. Especially important in evaluating postoperative unconsciousness are the symptoms associated with vascular cerebral sclerosis which appear suddenly and defy immediate explanation. Frequently this condition is encountered following short episodes of hypotension. It is often difficult to separate this disturbance from brain metastases.

Respiratory Causes

Disturbances caused by respiratory factors are due to defects in the external respiration, i.e., mechanical derangements of respiration, tracheobronchial obstruction, or rib fractures; or they may originate within the lungs: disturbed alveolar ventilation, pulmonary emphysema, pulmonary edema, diminution of the respiratory surface as in pulmonary collapse, hypostatic pneumonia or atelectasis. Nor should a central respiratory depression and the consequences of an insufficient artificial respiration be forgotten.

Hemodynamic Factors

The hemodynamic factors which may give rise to a depressed state of consciousness in the surgical patient are hypotension, hypovolemia, shock of short or long duration, and all forms of cardiovascular dysfunction including circulatory arrest, thrombosis and embolism. Massive hemorrhage from accident as well as from elective surgery is a frequent

cause. Fat embolism is not only followed by circulatory insufficiency, but it may also cause cerebral defects.

Infectious-Toxic Factors

Disturbances of consciousness of infectious-toxic origin may be caused by febrile infections, but especially by surgical complications such as wound infections, ileus, peritonitis, abscesses, phlegmony, empyema and septicemia (Figure 2). This particular group is of special interest to the surgeon because of frequency of occurrence as well as of its severe prognosis. In comparison with this group tetanus is now of secondary importance. The frequency of delirium due to alcohol withdrawal is surprisingly high.

Chemical Imbalance

Fluid and electrolyte imbalance as well as acid base derangements may be considered metabolic in origin (Figure 3). Further metabolic derangements are liver diseases and renal insufficiency, especially primary liver or renal disease with subsequent hepatic encephalopathy and liver coma or with uremia. Parenchymal disease with the danger of hepatorenal insufficiency may be considered a surgical complication. Endocrine disease with metabolic coma also belongs in this group.

Discussion

Our observations indicate that a number of diseases may lead to disturbances of consciousness. Although the causative factors may be known, they do not explain the pathogenesis. All derangements of consciousness are basically central events.[13] A diffuse destruction to the cortex may lead to derangement of consciousness.[9] In these cases there is a relationship between consciousness and the frequency of discharge from the cortical neurons.[3] Most extra-cerebral mechanisms cause such hypometabolism of ganglionic cells. Another group of consciousness disturbances may be caused by an upset of the sleep-wakefulness mechanisms located in the brain stem.[9]

The histopathological findings are merely in-

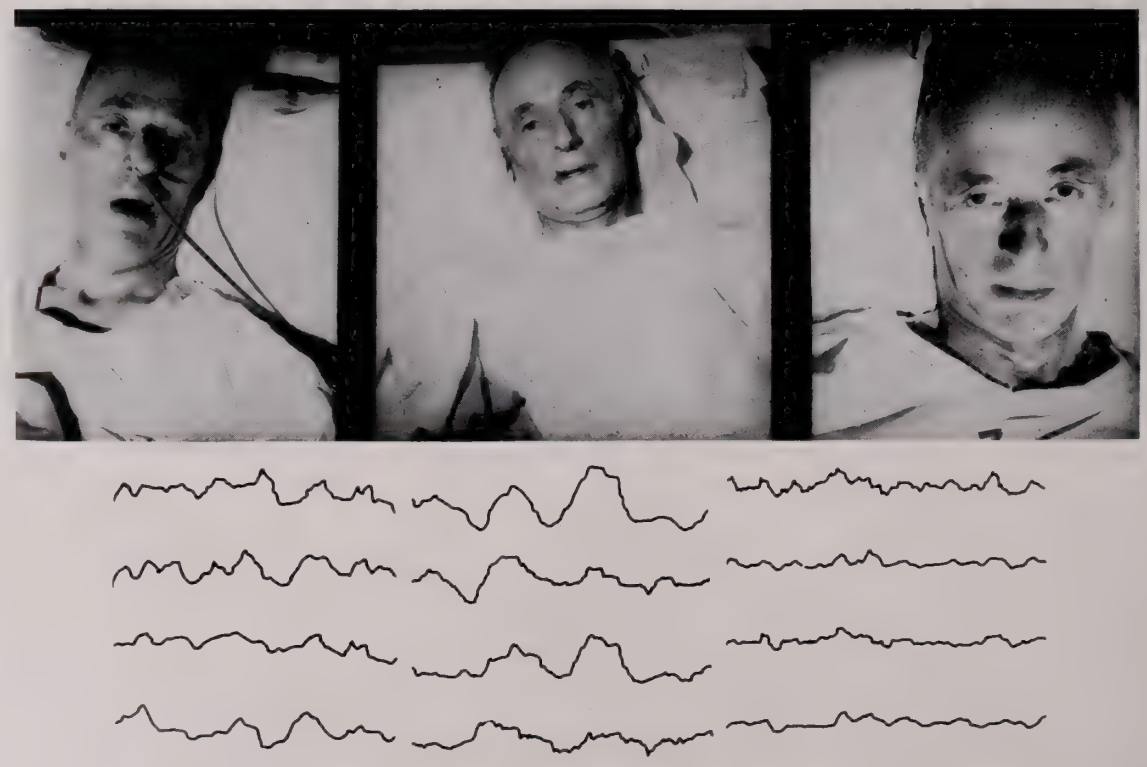

Fig. 2—Symptomatic psychosis in a 63-year-old with ileus and peritonitis. (a-left). Paranoid-hallucinatory transient syndrome with mild impairment of state of wakefulness. Electroencephalogram: Mild general changes. (b-middle). Acute mental disturbance. Electroencephalogram: Delta-rhythm, grouped (delta parenrhythmia). (c-right). Reversion in amnestic-affective transient syndrome. Electroencephalogram: Border-line mild general change.

dicative of local circulatory impairment.[13] These histological changes are caused by hypoxemia or by deficient cell nutrition or deficient elimination of waste products.[11] Chronic states of hypoxemia do not usually lead to cell death and necrosis but result in diminished cell volume, especially in certain centers, the so-called topistic units.[21]

Traumatic Brain Damage

A brain damaged by trauma or disease is very sensitive to any additional limitation of oxygen or energy supply.[8] While relatively slight noxious effects have no detrimental result on consciousness and brain function in the normal person, they may lead to disturbances of consciousness or even death when they act

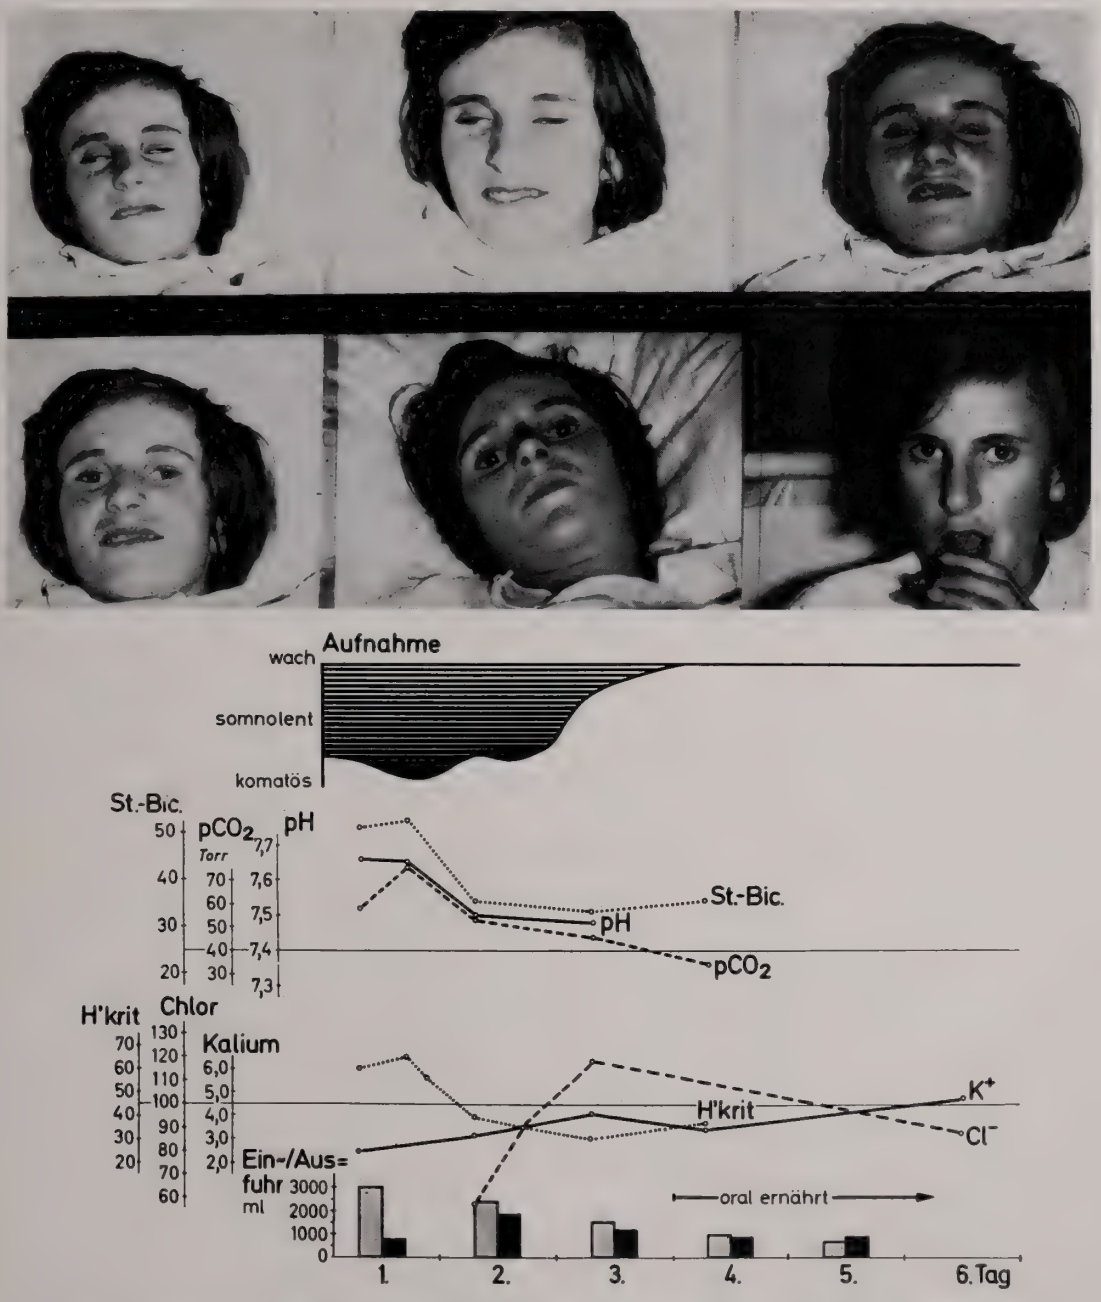

Fig. 3.—Observation during the course of an acute consciousness disturbance in hypochloremic-hypocalcemic alkalosis with dehydration following gastric-atony and fluid loss after blunt abdominal trauma in a 13-year-old girl. Clearing of consciousness and healing after correct substitution.

upon a brain of augmented vulnerability. Aside from direct cerebral damage a skull-brain trauma thus conditions the brain for secondary damaging effects as has been demonstrated by Selye for other diseases. In some instances we have seen how minor skull damage led to disturbances of consciousness in cases where a preceding brain injury had apparently been overcome. Furthermore, a simultaneous skull and brain injury may mask trauma to other organs and cloud their symptomatology.

Respiratory Insufficiency

Disturbances of consciousness in respiratory insufficiency are not so much the immediate consequence of hypoxia as that of respiratory acidosis or alkalosis. In these cases a relationship between the partial CO_2 pressure and the pH of the arterial blood is apparent to the changes of the consciousness level.[5] These derangements of the consciousness level obviously appear when the cerebral circulation (which depends on the systemic blood pressure) falls below a critical value or the oxygen content of the blood drops drastically for short periods of time.[15] A short period of ischemia acts more promptly and more profoundly than anoxemia.[13] The cerebral circulation may be insufficient in the presence of persistent heart action.

Infectious-Toxic Derangement

The pathogenesis of infectious-toxic derangements of the consciousness level is complex. Even simple infections lead to changes in vascular permeability for which histamine-like substances may be responsible. A serum permeability factor has been isolated.[22] While bacterial exotoxins do not lead to disturbances of the conscious mind,[12] endotoxins are known to cause cerebral swelling, hemorrhage, thrombosis and vascular damage.[2] Fever per se is not considered the cause of acute psychoses.[12] Alcoholic withdrawal delirium was found surprisingly frequently among our patients, at times with classical psychopathological and electroencephalographic symptoms. These patients demand special attention on account of their threatened secondary metabolic complications and the danger of infection. Fortunately our mortality in this group was less than the 30% reported by Tasca.

Chemical Imbalance

Water and electrolyte imbalances are most often the consequence of other diseases and rarely the primary defect.[6] Potassium deficiency states may be mentioned whose relationship to postoperative psychoses has been pointed out recently by Schwaiger and Staib.

Hypochloremia, even of moderate degree, may lead to derangement of the consciousness level. A number of metabolites have been implicated in the pathogenesis of hepatic coma, although a strict correlation has not been found.[10] There is a correlation between hepatic uremic disturbance of consciousness as evidenced by clinical findings and by biochemical investigations with acetoin and butylenglycol elevations.[20] A definitive diagnosis of metabolic coma due to endocrine derangement depends largely on the clinical symptomatology.

The two leading causes in the pathogenesis of unconsciousness are lack of oxygen and defects in the utilization of glucose, since the brain metabolism depends almost entirely on the oxidation of glucose.[7] Basically, all disturbances of the consciousness level are caused by a dysfunction of the cell membrane and of the cell itself. The high mortality of 39% in surgical patients with derangement of the consciousness level demonstrates the importance and the severe prognosis of this complication. Every disturbance of the state of wakefulness which occurs in the course of a surgical illness aggravates the prognosis.[4] One abnormal laboratory finding alone does not necessarily indicate a disturbance of the consciousness level or of the psychic behavior. These disturbances are usually the consequence of a complex derangement caused by a number of factors. Repeated examinations with determination of important functional entities and especially clinical experience provide the prognostic clues. The physical cause, often a surgical disease, must be found. Only complete correction offers the possibility of cure.

Summary

Disturbances of the consciousness level are alarming signals. They occur in the course of surgical diseases and have, in our experience, a mortality of 39%. The somatic causes for a

symptomatic psychosis are numerous. The etiology includes organic brain damage: respiratory, hemodynamic, infectious-toxic and primary metabolic causes. The pathogenesis is usually complex, combining a number of factors. Cerebral hypoxemia and disturbed glucose utilization of the brain are of special pathogenetic importance.

Prayer of a Discouraged Young Man

Lord, I call unto thee from the depth of my disheartened spirit. My will wavers and falters and fails. My hopes of yesterday, so buoyant and so brilliant, today have ended in the ashes of disappointment. My plans are cruelly thwarted. I am beaten by the buffetings of life and scarcely can find the strength in my hands and the resolution in my heart to take up again the broken threads of effort and of ambition.

Buttress, O Lord, my wavering will. Give fire and life again to my flagging hopes. Show me that the plan which failed today will but gird me for a wiser plan tomorrow. Enable my heart to see that my buffetings may but beat into me a greater strength. Nerve thou my flagging hands and enable me again to reach forth gladly for the toil and the gifts of life.

And above all, give me wisdom to see that my only final failure will be within myself, and that if my spirit fails not, I have found success. Amen.

P. R. Hayward

Draft Board Classification

In spite of the emphasis being put on bodily fitness for military service, it is not the thing America needs most. To develop military and naval geniuses is more important for the national security. There is no formula for this, but physical fitness is not necessarily the key. Many of the world's greatest military figures would have been rejected by the draft boards for these reasons:

George Washington, false teeth; Bismarck, overweight; Napoleon, ulcers of the stomach; U. S. Grant, alcoholism; Julius Caesar, epilepsy; Horatio Nelson, one eye, one arm; Kaiser Wilhelm, withered arm; Duke of Wellington, underweight.*

*Dr. Logan Glendening, Nation's Business.

What fools indeed we mortals are
To lavish care upon a car,
With ne'er a bit of time to see
About our own machinery.—John Kendrick Bangs

The School of Salernum*

Traveling southeast from Naples in sunny Italy one arrives at the attractive and lively Tyrrhenian seaport of Salerno, dating back in proud antiquity to ancient Salernum, an early Roman health resort and subsequent site of the first medical school, the School of Salernum. Wandering into the "old" section of the historic town one might, with sufficient imagination (there are no identifiable ruins), recapture the aura of Civitas Hyppocratica, which flourished for centuries, reaching its pinnacle of fame and glory in the 11th and 12th centuries.

How the School became the apotheosis of medical wisdom is a familiar and fascinating story: the medieval phenomenon of eclecticism whereby scattered and isolated cultures gravitated to favorable centers to pool their individual contributions. Salernum became such a center: medical savants from all over the then civilized world congregated to share and amalgamate their knowledge. It has appropriately been said that the School was founded by a Latin, a Greek, an Arab, and a Jew, thus becoming the collector, repository, and transmitter of the best medical wisdom then extant.

Students flocked to Salernum from near and far to observe and learn. A constant stream of patients came and went, the bulk of them Crusaders with the multifarious diseases and injuries acquired on their pilgrimages to and from the Holy Land.

Just as any Mecca becomes a magnet, so did the School of Salernum.

The magnum opus of that illustrious period was the Regimen Sanitatis Salerni, composed by the doctors of the School to serve as a directive for physicians and a handbook of home medicine for the layman. Its manifest objective was to motivate its lay readers to respect professional advice (if they could get it), to use common sense in self-prescribing and treatment, and to divest themselves of medical superstitions.

In tone the Regimen is alternately serious and jocular, naive and sardonic—with an occasional malicious jibe at physicians for their pedantry and laymen for their adherence to folk fallacies.

In literary form it is a collection of succinct Latin aphorisms, brilliantly translated into 16th-century English by the distinguished Elizabethan poet, Sir John Harington, who has so consummately captured the blithe spirit and ineffable charm of the original.

The quintessential quality and flavor of the Regimen is invested in a single couplet:

"Use three Physicians still; first Doctor Quiet,
Next Doctor Merry-man, and Doctor Dyet."

Editor's Note: This introduction will be followed in subsequent issues by extracts and analyses from the School of Salernum.

Law

When I hear any man talk of an unalterable law the only effect it produces upon me is to convince me that he is an unalterable fool.—Sydney Smith

Portal Hypertension Varicose Vein Bleeding and Shunt Operation

PROFESSOR GÜTGEMANN, M.D.*
GREGOR ESSER, M.D.*
Bonn, West Germany

IN 1751 GEORGE ERNST STAHL described correctly in his doctor's thesis, entitled "De vena portae, porta malorum," the syndrome of portal hypertension in liver cirrhosis. More than one century later this disease attracted the attention of surgeons when the preliminary animal experiments of Nikolaus Eck became known in 1877. Lenoir in France performed the first portacaval anastomosis in a patient with decompensated liver cirrhosis, for alleviation of ascites. Vidal, in 1903, was the first to recommend portacaval anastomosis for the treatment of bleeding esophageal varices, at the 16th French Congress of Surgery. One patient operated by him in 1904 for ascites survived; however, it recurred after six weeks. Rosenstein in Germany had the first lasting success in 1912 in treating ascites with portacaval anastomosis in a 60-year-old woman.

There were scattered reports of this operation in the following years: by Kleinschmidt in 1935 and Jusbasic in 1939. Portacaval shunt operations were finally firmly established and publicized with the successful work of Whipple, Blakemore and Lord for the therapy and prophylaxis of varicose-vein bleeding in portal hypertension.

This report is based on experience of the last fifteen years with 725 patients suffering from portal hypertension, on whom + 353 portacaval shunt operations were performed.

Etiology

Intrahepatic Blocks

The vascular occlusion within the liver and the so-called intrahepatic block is an unsatisfactory explanation; for, when the portal vein is transected at its entrance into the liver and then anastomosed end to side with the vena cava, neither does the pre-sinusoidal pressure become normal despite a 60 percent reduction of the blood supply to the liver, nor is there a return to normal blood pressure in the epiploic

*Department of Surgery and Policlinic, University of Bonn. Director: Professor Alfred Gütgemann, M.D.

veins which are presumably decompressed.

Liver Cirrhosis

The main cause of portal hypertension is liver cirrhosis. The underlying disease, however, differs with geographic location and social status. In the United States 60 to 80 percent of cirrhoses are caused by alcohol abuse, and the figure in France is 80 percent. In our area alcoholic cirrhosis accounts for 15 to 20 percent, while post-hepatitic cirrhosis is responsible for 80 percent.

Bilharziosis

Bilharziosis is the prevailing causative liver disease in certain regions, especially in Egypt, Mesopotamia, Madagascar, Brazil, Venezuela, Japan, China, Formosa, the Philippines and Indonesia. It is distinguished by two factors: (1) the hepatic parenchymal tolerance in bilharziosis is considerably greater than in alcoholic-toxic or post-hepatitic liver cirrhosis, and (2) the portal-hypertension in bilharziosis of the liver causes a pre-sinusoidal block as contrasted with the post-sinusoidal block in liver cirrhosis.

Hepatitis

There has been a steady increase in the incidence of hepatitis in our part of the world. About 10 years ago the incidence of hepatitis without jaundice was estimated as 20 percent of all hepatitis cases. Systematic investigations during the last few years revealed a percentage of 40 to 60 percent. The incidence of liver disease approximates that of diabetes. Burgmann estimated in 1963 the annual number of fatal hemorrhages due to liver cirrhosis in Germany as 3,500. Considering this figure, the number of operations performed must be considered small, in our area as well as in the rest of the world.

Complications of Portal-Hypertension

Varicose Vein Bleeding

Varicose vein bleeding, the most serious complication of portal hypertension, makes it a surgical disease. About 40 to 60 percent of all patients with liver cirrhosis develop portal hypertension, and approximately 60 percent of these bleed from varicose veins.

Figure 2

Pre-hepatic and post-hepatic vein obstructions are responsible for portal hypertension in approximately 15 percent. Acute hemorrhage from varicose veins due to liver cirrhosis is always a life-threatening event. Of all gastrointestinal bleeding it carries the worst prognosis.

Hepatic Coma

The aggravating factors to increase the danger of hepatic coma are: (1) the usually huge blood loss; (2) the early failure of autonomic compensatory mechanisms in a state of acute low blood volume; and (3) the sensitivity of the damaged liver to hypoxia. In this state of circulatory centralization the liver acts as a peripheral organ.

The surviving rate from acute hemorrhage in relation to the number of bleeding episodes is shown in Figure 1. The prevailing causes of death are hemorrhage and hepatic coma (Figure 2). The mortality of acute varicose vein hemorrhage as reported in the literature is shown in Figure 3.

Mortality in Acute Bleeding of Varices

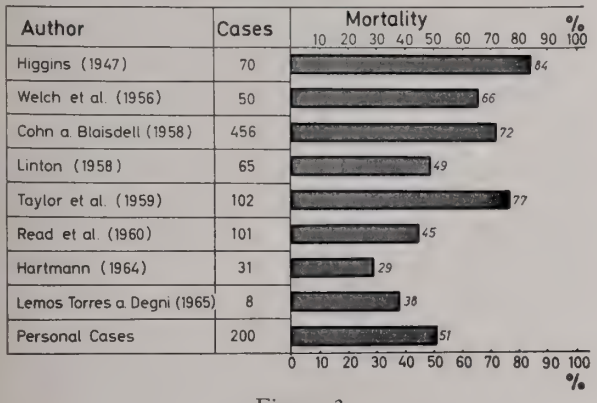

Figure 3

Treatment

The treatment of acute varicose vein bleeding is a very demanding task, and the decision for immediate operative intervention or for a conservative trial must be individualized. We have operated on 72 patients with varicose vein bleeding selected from 200 patients with this disorder (Figure 4). The best permanent results are obtained with portacaval anastomoses; however, the mortality with such a procedure is still quite high (Figure 5). The last 13 emergency shunt operations were successful in 11 cases (85%).

Our experience with 252 patients suffering from acute varicose vein bleeding has led us to establish the following therapeutic guidelines.

Prompt Replacement of Blood Loss

Any kind of varicose vein bleeding demands a prompt volume replacement, if at all possible, with blood. The damaged liver is quite sensitive to hypoxia.

Emergency Surgical Treatment of Cases with Acute Bleeding Oesophageal Varices

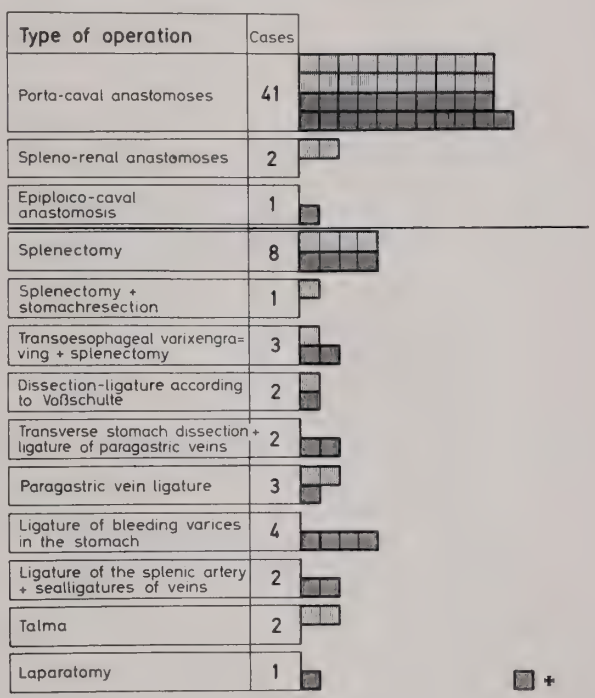

Figure 4

Portacaval Anastomosis as Emergency Operation

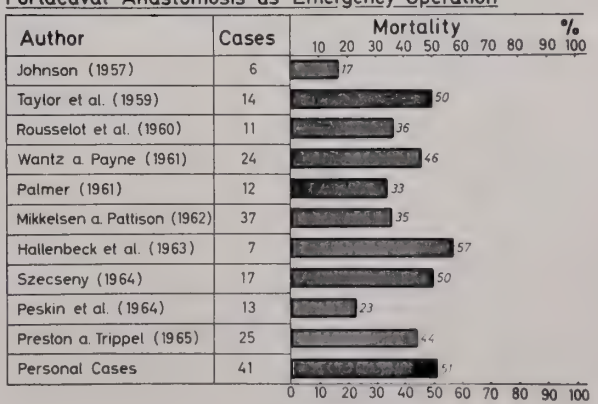

Figure 5

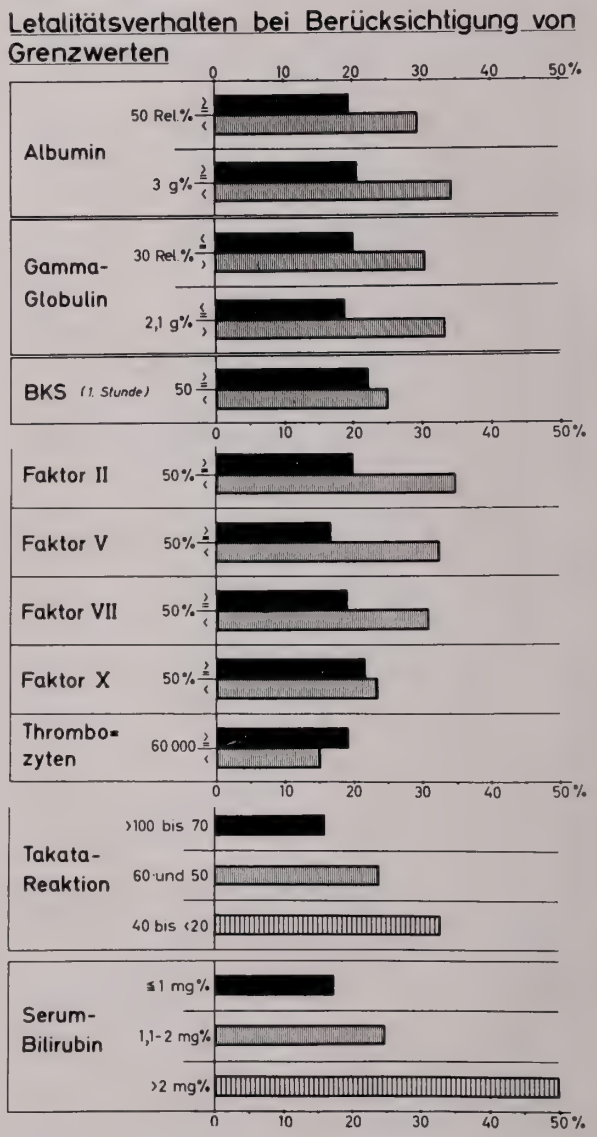
Conservative Management

Tamponage of the varices with a double balloon tube, as a rule, stops varix bleeding immediately. Important is early administration of laxatives and enemas in order to evacuate blood from the gut. Oral administration of antibiotics active against coliform bacilli (for example 2 to 5 grams neomycin within a 24-hour period) and conventional liver therapy are part of the medical regime.

Shunt Operation

In cases of incipient hemorrhage, especially in first occurrence of hemorrhage, an immediate shunt operation is desirable. If the liver function is satisfactory and the blood loss has been replaced rapidly, a delay is not justified.



The operation should be carried out when the bowel has been cleared of blood, still with double balloon tube in place, about one or two days after onset of bleeding. In poor-risk cases we prefer the spleno-renal shunt.

A shunt procedure after the hemorrhage has ceased is the best measure to prevent recurrence of varicose vein bleeding. At present the portacaval anastomosis is virtually without competition as the most efficient modality for the treatment of hemorrhage and ascites.

The operative success of a shunt operation depends on the proper selection of patients. Ascites is a severe complication of portal hypertension; it is a sign of decompensation and must be eliminated before elective surgery is performed. Other important preconditions for a successful shunt operation are good general condition, a sufficient cardiac and circulatory function and a generally adaptable organism: to wit, the patient should not be too old. The choice of operative procedure and the indication for operation are determined by the anatomy of the portal system as demonstrated in splenoportography. The status of the liver functions, too, determines the indications and choice of procedure, and it is important to know that the liver function is satisfactory as evidenced by: (a) bilirubin under 2 mg %; (b) takata reaction above 40 mg %; (c) albumin above 3 gr %; (d) gamma-globulin below 30 rel. %; (e) coagulation factors II, V, VII above 50%; and (f) cholinesterase above 1600 mU.

Palliative Operations

If shunt operations are impossible and conservative treatment fails or if the hemorrhage recurs after removal of the double balloon tube, operative hemostasis at the point of hemorrhage may be tried. However, this is indicated only if liver functions have not deteriorated markedly as evidenced by incipient or manifest hepatic coma. When hepatic coma is present all methods of therapy fail, as a rule; any operation at this stage hastens the demise of the patient.

Translated: Mortality Patterns as Pertains to Borderline Tests.

Figure 6

Diuretics

In the days of surgical pioneering, ascites was the main indication for shunt operations; but the development of powerful diuretics, especially of the salt diuretics and of the aldosterone antagonists, has made it possible to control ascites due to liver cirrhosis by conservative means. We have treated 150 patients with liver cirrhosis and ascites without performing any portacaval anastomosis. Two patients were resistant to this therapy; one had a primary hepatocellular carcinoma and the other was a 65-year-old woman with abdominal carcinomatosis due to a primary breast cancer.

Mortality

Figure 6 shows the mortality in portacaval anastomosis in 225 patients in relation to some preoperative liver function tests. This includes 40 emergency operations which carried a mortality of 50%.

We have found needle- or open-liver biopsies unreliable as criteria for the operative procedure; these morphologic findings reflect only the status of one small portion of the liver. In cirrhosis especially one often finds varying degrees of inflammation and necrosis in different areas of the liver. However, if a small liver is found on the splenoportogram one may assume that only a small volume of

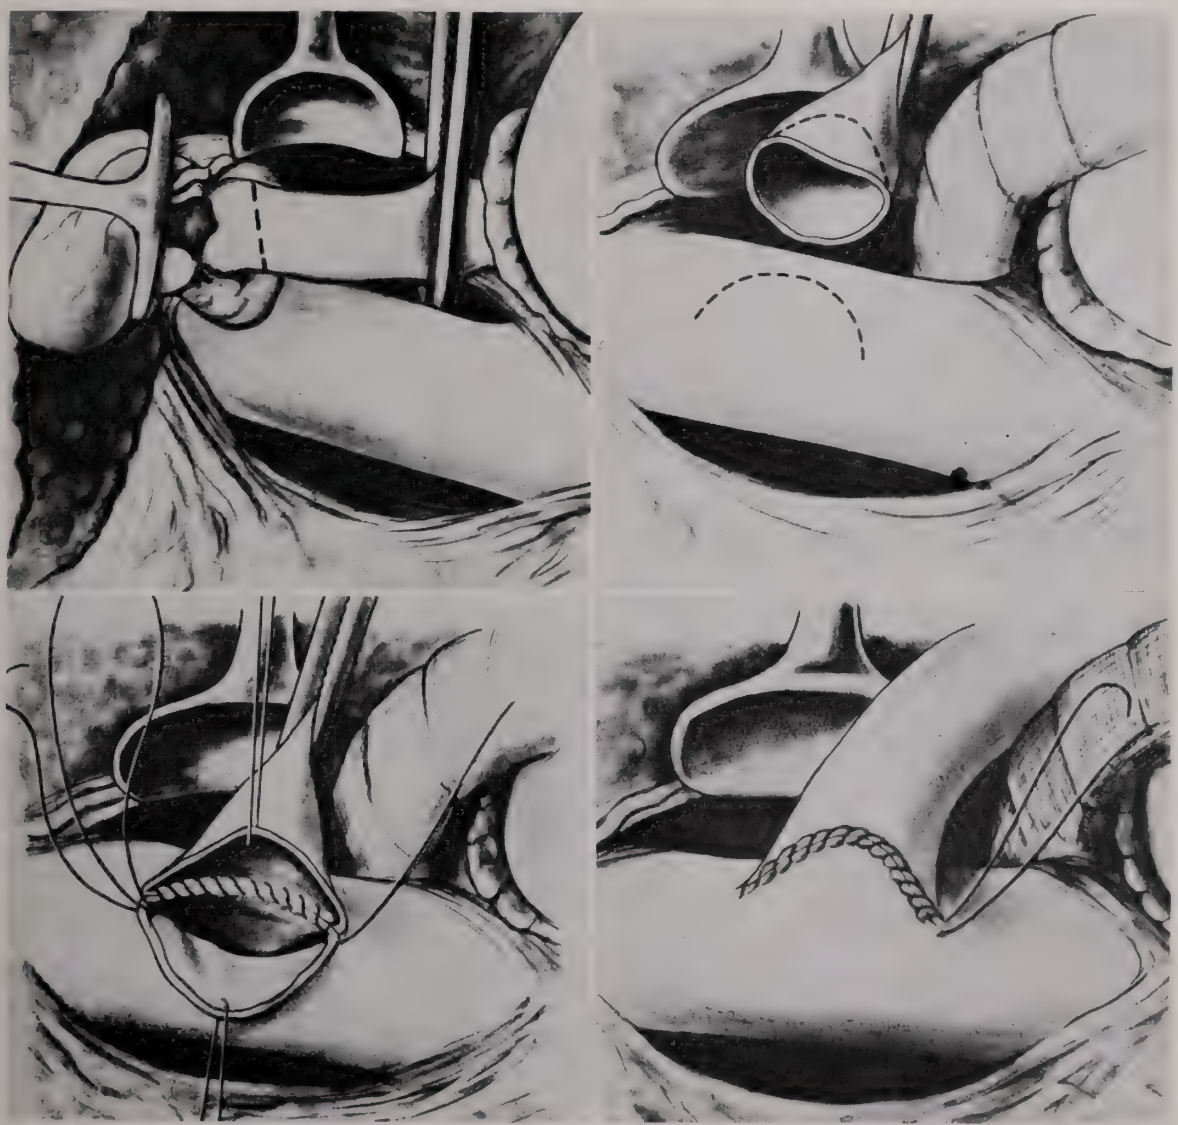


Fig. 7 (a-top left, b-top right, c-bottom left, d-bottom right)—Technique of termino-lateral portacaval anastomosis with flap formation.

liver cells is present, indicative of a small compensatory potential unable to handle the abrupt circulatory changes induced by a portacaval anastomosis.

Surgical Treatment

Portacaval Anastomosis

Two hundred eighty-four direct portacaval anastomoses were performed prior to March 15, 1968. Fifty-six were side-to-side and 228 end-to-side anastomoses. Fifty shunts were performed as an emergency for acute hemorrhage from varices—with a mortality of 48% (24 cases). The operative mortality, including the first 28 postoperative days, in 234 elective operations was 14.5% (34 cases).

The incidence of recurrent hemorrhages has been lowered by the use of a special technique for widening of the portal vein anastomosis (Figures 7a-d and 8a-d). Early recurrent hemorrhage occurred in 16 patients after portacaval anastomoses (5.6%), most of them from persistent varices after emergency operations (Table). Late hemorrhages occurred in five cases (1.8%).

Spleno-renal Anastomosis

Spleno-renal anastomoses are performed in patients with thrombosis of the portal vein and with a patent splenic vein available down to its junction with the superior mesenteric vein. During recent years we have also performed this operation in patients whose laboratory values indicated an increased risk for a direct portacaval shunt. If the spleno-renal anastomosis is wide enough it sufficiently decompresses the portal system and the varicose veins of the esophagus and stomach. The deprivation of the liver's venous blood supply is considerably less than in completely interrupting the portal vein blood flow to the liver. Our technique of spleno-renal anastomosis corresponds with our technique of portacaval anastomosis. The anastomosis should be made as far centrally between the splenic vein and the renal vein as possible. We have performed 35 spleno-renal anastomoses up to March 15, 1968, ten of them for a prehepatic obstruction and 25 for liver cirrhosis. The mortality in patients with cirrhosis and spleno-renal shunt, if done during the interval, was 8.3% (24 patients, two deaths). We lost one patient with a spleno-renal anastomosis performed for prehepatic obstruction. This was a 4½-year-old girl—the first shunt operation in our hospital.

Spleno-renal anastomosis should be performed as an emergency operation in bleeding varicose veins due to liver cirrhosis, if the risk for direct portacaval shunt is too high.

In our experience recurrent hemorrhage after a spleno-renal anastomosis is no more frequent than after a direct portacaval anastomosis. There was recurrent hemorrhage in two patients after elective surgery among 24 patients with liver cirrhosis (8.3%). Nine patients operated upon for prehepatic block and hemorrhage had no recurrent hemorrhage. Only the 4½-year-old child mentioned above suffered recurrent hemorrhage.

Coronaria-Caval Anastomosis

When the great coronary vein is widely patent we perform a coronaria-caval anastomosis for the lowering of the elevated portal vein pressure. We have done this in eight cases. For this we use the shortest route of vascular connection through the foramen of Winslow. This operation makes good sense as long as the width of the coronary vein

TABLE

Thrombosis of normal-appearing portal vein	2	2	1	1

*Both cases are free of recurrence after spleno-renal anastomoses.

equals at least that of the portal vein. This anastomosis has been performed in six patients with liver cirrhosis and two with prehepatic block. There were no deaths and no recurrence of bleeding.

Mesenterico-Caval Anastomosis

A mesenterico-caval anastomosis was done in three patients. An omphalico-caval and an epiploico-caval anastomosis were done in one patient each. The latter thrombosed very fast.

During the shunt operation special attention should be paid to the possibility of stomach ulcers and gallstone disease. In 5% of our patients with liver cirrhosis we found gastric ulcers. Furthermore, we know of three cases who bled to death from gastric or duodenal ulcers several years after an apparently successful portacaval anastomosis. One patient died two years after the shunt operation from undiagnosed choledocholithiasis. Therefore, for the past ten years we have removed the gallbladder, if it contains stones, at the time of the shunt operation. In one female patient we performed at the same time a common bile duct exploration and a papillolithotomy.

Portacaval anastomoses, whether of the di-

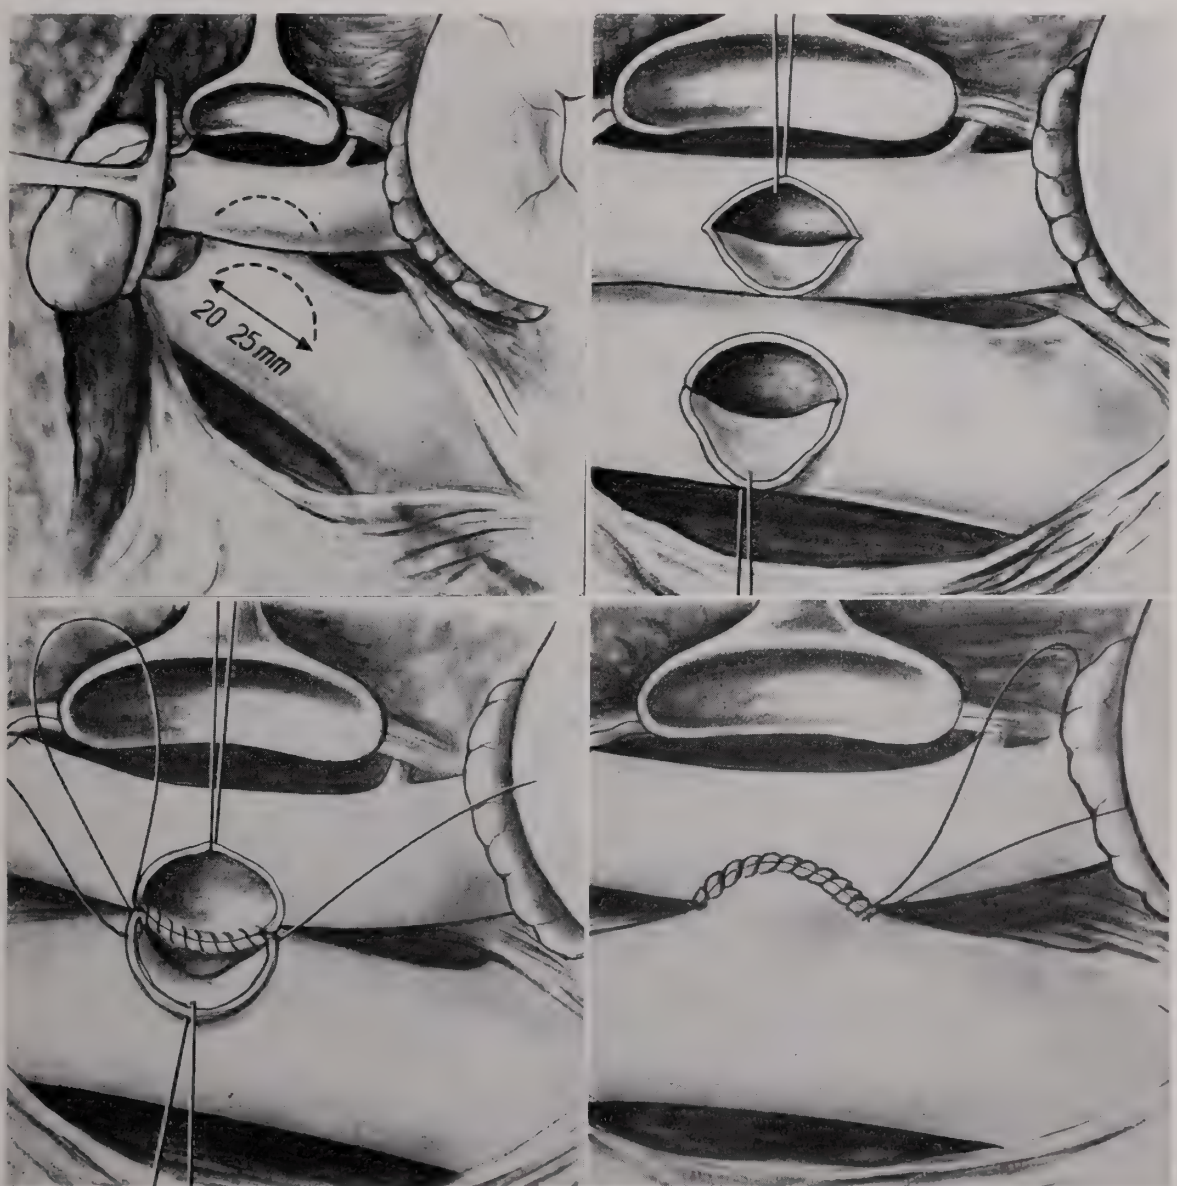

Fig. 8 (a-top left, b-top right, c-bottom left, d-bottom right)—Technique of latero-lateral portacaval anastomosis with flap formation.

rect or indirect type, insure freedom from recurrent hemorrhage. The operative risk is low when the proper indications are observed, and the proper operative technique insures freedom from recurrence. Acute varicose vein bleeding and cases where the operative indication is not clear-cut pose particular problems.

Encephalopathy

Portacaval anastomosis could well be considered the ideal method of treatment for complications of portal hypertension in liver cirrhosis were it not for the occasional occurrence of encephalopathy. Long-term observations have shown us that a portacaval anastomosis does not cause any additional liver damage. We have performed electroencephalographic and psychoanalytic examinations in cooperation with Dr. Penin (Department of Neurology, University Hospitals, Director Professor Dr. H. J. Weitbrecht) in more than 300 patients with liver cirrhosis and portal hypertension. The incidence of encephalopathy from hepatoportal origin and the speed of its development in non-operated patients (142 cases) and operated patients (114 cases) were equal. The degree of seriousness was also equally distributed; however, there were more acute forms in the group of patients who had undergone shunt operations, while the non-operated group contained more chronic forms. During an eight-year observation period of patients with portacaval anastomoses, the personality pattern of one third of the patients was without significance: one third had undergone no change after the operation, and one third had worsened during the period of observation. The psychic improvement of one third of the patients with portacaval anastomosis and cirrhosis came as a surprise.

Liver Function or Encephalopathy

There was a clear correlation between the degree of encephalopathy, as evidenced by psychopathological and electroencephalographic findings, and the liver function tests: the greater the depression of liver function, the higher the rate of encephalopathy.

At the present time it is still impossible to predict which patient will show personality changes after a portacaval anastomosis. There is little doubt that patients with markedly depressed liver functions are the most likely candidates. Cirrhotics with encephalopathy should not be subjected to a shunt operation.

Prophylactic Shunt

We perform prophylactic shunt operations only with great reluctance. This is based on the facts that only 60 percent of patients with varicose veins bleed, that the operative mortality is still high, and that there is always the threat of an acute postoperative encephalopathy. Our criteria for a prophylactic portacaval anastomosis are: (1) good general condition; (2) good liver function; and (3) pronounced esophageal varices in the absence of a caudally directed collateral circulation, as shown in serial splenoportograms.

Summary

Portacaval anastomosis has been a very useful operation in the treatment of life-threatening varicose vein bleeding due to portal hypertension in liver cirrhosis. The favorable early and late results should not deter us from seeking better operative procedures or conservative measures for the elimination of the danger of hemorrhage. With a proper patient selection the mortality is relatively low. Emergency operations in acute varicose vein bleeding, however, show a high operative mortality; but even in those circumstances the portacaval anastomosis, if done in time, is still the most effective treatment.

In cases with borderline liver function, a spleno-renal anatomosis is the procedure of choice.

A portacaval anastomosis does not cause additional permanent liver damage. Postoperative encephalopathy does not occur more frequently or more severely than in patients with varicose veins without a shunt operation. However, shunt operations cause more acute encephalopathies.

Ascites, once an indication for shunt operation, has become the domain of medical therapy. One should hope that further search for causes of portal hypertension may yield some specific drugs for an efficient lowering of the

portal hypertension. The portacaval anastomosis, even if it mimicks nature's efforts of collateralization, is still an unphysiological measure. It is therapeutically effective and tolerated to some extent by the organism, but it has its risks and is directed against only one complication rather than against the basic disease. Thus the whole problem still calls for a better solution.

Great things can be reduced to small things, and small things can be reduced to nothing.—Chinese Proverb

Nobel Prize Winners in Medicine and Physiology

Camillo Golgi 1906

Santiago Ramon Y Cajal 1906

In recognition of their work on the structure of the nervous system.

"I have found two quite different kinds of nerve-endings in the tendons:

"(a) The one is represented by peculiar bodies which are quite characteristic in appearance, form, structure, and type of connection with the nerve fibrils, and are unlike any other in the known nervous end-apparatus of our organism; it is very probable, then, that their significance lies in correspondence with the function which muscles and tendons have to perform in common.

"(b) The other type is represented by bodies which likewise have a peculiar and striking appearance, but which, on the whole, find their counterparts in other known nervous end-organs of our bodies, which they resemble not only in anatomical structure but probably in function also.

"The principal anatomical characteristics of the musculo-tendinous organs can be summed up briefly as follows:

"In general they are spindle-shaped, and one of their ends is always connected with the fasciculi of the muscle fibers.

"Their size varies within fairly wide limits, from 70-80 microns in breadth and 300-400 microns in length to 100-120 microns in breadth and over 800 microns in length.

"Their outline tends to be very distinct and even appears at times in the form of a slender, glittering border, along which one catches sight of nuclei."

Besides his work in neuroanatomy, particularly his discovery of the neurons (Golgi cells), Golgi is distinguished for his later research in neuropathology.

"From the sum of my researches springs a general concept which comprehends the following propositions:

"The nerve cells are morphologic units, the neurons. . . . The morphologic dispositions attest that the nerve elements have reciprocal relations of *contiguity* and not of *continuity*.

"These facts involve three physiological postulates:

"(1) Since nature, in order to assure and amplify contacts, has created complicated systems of ramifications around the cells, it is necessary to admit that the nervous currents are transmitted from one element to another by virtue of a sort of induction, or influence at a distance.

"(2) It is also necessary to suppose that the cellular bodies and the dendritic prolongations are induction apparatus, since they represent intermediate links between the afferent nerve fibers and the axons.

"(3) Examination of the transmission of nerve impulses in the sense organs shows that the movement of the nerve impulse is *toward the cell body*, whereas in the axons it is *away from the cell body*."

The abridged quotation above summarizes Cajal's investigations complementing Golgi's discoveries. Cajal's research, in turn, became the point of departure for the work of Charles Sherrington and Egas Moniz.*

Problems and Operative Technique in Portacaval Anastomoses

GREGOR ESSER, M.D.*
Bonn, West Germany

PORTACAVAL ANASTOMOSES in patients with liver cirrhosis and portal hypertension have been used for 23 years for the treatment of bleeding varices from the upper digestive tract. The operation has been performed only in certain centers of different countries and continents. This geographic concentration has enhanced the systematic exploration of the pre- and postoperative pathophysiology. Long-term observations have made it possible to establish definite indications for shunt operations.

This communication is based on an operative experience with 360 patients who underwent direct or indirect portacaval anastomoses. The first shunt operation in Bonn, Germany was performed 15 years ago by Gütgemann. Since then surgery of the portal vein has, under his direction, developed into a special field of interest and research.

Some technical improvements which we introduced have proved of value and are worth reporting.

Selection of Patients

Criteria for patient selection with portal hypertension are the general and circulatory condition, the age of the patient, and the liver function (Table 1). A preoperative percutane-

TABLE 1

Criteria in the Selection of Patients with Liver Cirrhosis for Portacaval Anastomoses

1.	Good general condition	
2.	Good circulatory status	
3.	Portal vein free of thrombi	
4.	Adequate liver size (on splenoportogram)	
5.	Bilirubin	under 2 mg%
6.	Takata	above 40 mg%
7.	Serum albumin	above 3 gr%
8.	Cholinesterase	above 1600 mμ
9.	Prothrombin	above 50 %
10.	Factor V	above 50 %
11.	Factor VII	above 50 %

ous splenoportogram determines the operative method. As a rule, patients with several bleeding episodes from varices of the esophagus or the stomach are selected for operation. The prophylactic shunt operations require stringent criteria with regard to liver function. They should be reserved for cases with a definite bleeding tendency and marked esophageal varices, as demonstrated in splenoportogram, and predominantly cranial collateral circulation.

Preparation of Patient

The preoperative preparation of patients with liver cirrhosis and portal hypertension who have adequate liver function is the same as that for other patients with routine operations. Cirrhotics with liver decompensation require long-term medical therapy.

The anesthetic of choice used to be Halothane. We discontinued its use when we saw several cases of early postoperative coma after the use of this anesthetic, even though it is impossible to definitely implicate Halothane. We are now using neuroleptanalgesia* in patients with liver cirrhosis with excellent results. The patients awaken rapidly after the operation, regain their activity soon, and can leave their bed on the day after operation, able to eat or at least to drink.

The Operation

Incision

The operative approach for the portal vein is always satisfactory through a right subcostal incision which is extended laterally. Thoracoabdominal incisions are unnecessary. After mobilization of the duodenum, the hepatoduodenal ligament is elevated with a Rehn-spatula and the portal vein easily dissected on its lower border.

Operative Technique

The choice between an end-to-side or side-to-side anastomosis is optional and depends on the anatomical findings. Schreiber (1963) has proved that there is no difference between an end-to-side and side-to-side portacaval anastomosis with respect to blood flow and liver function. Thus it is unnecessary to insist on a side-to-side anastomosis between portal vein and inferior vena cava. The end-to-side anastomosis in most cases is technically easier and can be done faster. However, if anatomically feasible, we sometimes perform a side-to-side anastomosis.

Because we have seen several postoperative thromboses in the portal vein ramifications, when the transection was made at the bifurcation, which led to liver necrosis and death by coma, we now ligate the main branch of the portal vein far enough from the bifurcation to maintain a communication between the branches. Since we have started this practice we have not encountered early postoperative coma in operations which were done in the hemorrhage-free interval. The degree of postoperative leukocytosis has also definitely decreased with this practice. It may be assumed that there is a continuing circulation between the portal vein branches which prevents portal thrombosis in the liver branches.

Gütgemann has originated a very useful and successful anastomotic technique; by using his *flap formation* at the portacaval anastomosis

*See Test Your Word Score Page 1583.

Fig. 1—a (left), b (middle), c (right)—Schematic incision and suture of a termino-lateral portacaval anastomosis.

Fig. 2—a (top-left), b (top-right), c (bottom-left) and d (bottom-right)—Construction of a termino-lateral portacaval anastomosis.

it is possible to avoid anastomotic stenosis of the portal vein (Figures 1 and 2). The incidence of postoperative portal vein thrombosis cited in the literature is 4 to 20%. Using our operative technique we were able to lower it to 2%.

Anticoagulation

We have discontinued the use of *heparin* in portacaval anastomoses. When heparin was injected in high concentrations into the proximal portal vein segment after this was clamped off and before anastomosis was done, it appeared to damage the vein walls. Occasionally we have seen postoperative thrombosis of the anastomosed portal vein in the presence of a wide anastomosis, and we suspected a possible intimal reaction of the portal vein as a possible cause. After discontinuing heparin four years ago we have encountered no more postoperative thrombotic occlusion in portacaval anastomosis. Anticoagulation of the clamped proximal portal vein for the prevention of thrombosis during the anastomosis is unnecessary in our experience. There is increased fibrinolytic activity as a result of venous congestion. This makes it possible to interrupt the blood stream for up to 30 minutes without the danger of thrombus formation.

Complications

Ascitic flow through the drain site in the area of the portacaval anastomosis has been a nasty postoperative complication, presenting a real nursing problem. For days and weeks the patients were lying on wet pillows and had to be redressed up to 12 times a day. We suspected the cause to be the transection of distended retroperitoneal lymphatic vessels over the vena cava. We now *ligate the retroperitoneal tissue* during the dissection of the vena cava, thus eliminating this complication. At present we still drain for three to five days.

The *postoperative treatment* demands no particular measures. Our therapeutic regime is summarized in Table 2.

TABLE 2

Outline of Immediate Postoperative Management after Portacaval Anastomoses

1. After the wakening intravenous drip of 1500 ml until the next morning wih 50 meq potassium lactate.
2. Starting with the day of operation a daily liver cocktail with Laevulose, B-vitamins, adrenal cortical hormones and 5 million units penicillin for 10 days.
   To be injected: 1 gr vitamin C, 10 mg vitamin K_1
   By mouth: 200 mg Spironolactone for five days
   50 mg Spironolactone for five more days.
3. During the first three postoperative days fluid administration according to hematocrit value (base 40) by infusions with glucose, levulose, Ringer's solution. Potassium substitution.
4. Postoperative patients are permitted to drink on the first postoperative day and to have light meals if they desire. They are to walk around the bed from the first postoperative day on and are permitted to leave the room starting on the sixth postoperative day.

Comments and Conclusions

In view of the increased incidence of chronic parenchymal liver damage one may foresee a shortage of centers equipped for portal-vein surgery. Surgeons in other large institutions may be expected to add portacaval anastomosis to their operative repertoire, since the clinical and technical ground work has been done. In presenting special operative and technical aspects we hope to contribute to previously gained experience and to a reduction of operative failures. However, even more work is to be done in the search for new approaches to the alleviation of portal hypertension.

Years of investigation have led to a standardization in indication and operative technique of portacaval anastomosis for portal hypertension in liver cirrhosis. The neglect of small technical details can lead to failure. Some of these technical factors have been discussed. The operative technique has been briefly described, and a review of indications for operation and of postoperative management has been presented.

IN THE PAST we have repeatedly pointed out the surprising frequency of arterial hypertension in patients with urologic defects, particularly in cases of unilateral renal involvement (Table).

Selection of Patients

Diastolic pressures above 90 mm/Hg at rest were considered the criterion for arterial hypertension. For sharper differentiation a further subdivision of 193 cases was isolated from the 1964 to June 1967 list: ninety-three cases with diastolic pressures from 90-100 mm/Hg and 100 cases with diastolic pressures exceeding 100 mm/Hg.

These figures may appear rather high; however, we must remember that we are dealing with a selected group of patients who were referred for urological therapy. Thus our study will not permit conclusions concerning the frequency of renal hypertension compared to other causes of high blood pressure.

We can differentiate two groups among these patients.

Urologic Problems

The first category consisted of patients who were referred to the clinic primarily for the purpose of urological investigation or therapy, and whose hypertension either had been no factor at the time of their admission or had constituted only a secondary aspect. Usually no treatment had been administered for hypertension. This group included nephroptoses, hydronephroses, renal cysts, urinary tract calculi and renal tumors.

Renal Hypertension Problems

Comprising the second category were patients referred to us primarily because of renal hypertension, in whom medical treatment had been unsuccessful. This group included hypoplastic kidneys, renal artery stenosis, inflam-

*From the Urologic Section of the Surgical University Clinic, Bonn. Director: Professor A. Gütgemann, M.D.

matory contracted kidneys or pyelonephritis due to calculi.

Diagnosis

In these 446 cases of urologic disease with associated arterial hypertension we made every reasonable effort by means of history, para-urologic history, cardiologic, neurologic and metabolic investigation to rule out other than urologic causes of hypertension.

The high incidence of hypertension is not surprising when one considers the studies of J. A. Wilbur of the Georgia State Health Department, where the consecutive examinations of 3,000 people of Baldwin County, State of Georgia (U.S.A.), found 630 hypertensive persons of whom only 55% knew of their condition. Three hundred and forty-seven remembered that previously a physician had made the diagnosis of hypertension but in most cases had discontinued their medication after three months.

Only 352 of the 630 hypertensive patients in Wilbur's series had consulted a physician in the previous three years. One hundred and seventy-six needed treatment when they were seen at the State Health Department. Wilbur also pointed out that hypertension accounts for 5% of all deaths directly and can be considered an important complication in 13% of patients with another disease. He concluded that in the subsequent five years the lives of one million Americans could be saved if therapy could bbe instituted. Thus roughly outlined is the manner in which every physician can contribute to the eradication of the problem.

TABLE

Unilateral renal diseases	1950 - 1963 Diastol pressure above 90 mm Hg	1964 - 1967 Diastol. pressure 90 - 100 mm Hg	1964 - 1967 Diastol. pressure above 100 mm Hg	Total number

Distribution and interrelation of varied underlying defects in 446 patients who were admitted in the period from 1950 to June 1967 with renal defects and accompanying arterial hypertension.

Routine Blood Pressure

By taking the blood pressure of every patient, no matter what his presenting complaint, we are convinced that a considerably greater number of hypertensive patients will be found than had been assumed to exist.

Urologically speaking, recognition of therapeutic peculiarities in hypertensive patients means that arterial hypertension must be strongly considered in the therapeutic measures. Not only the pathological-anatomical state of the affected organ has to be taken into consideration but also to what extent the chosen therapy might be effective for hypertension. Such considerations presume that routine urologic examination should be completed by additional studies as soon as paroxysmal or constant arterial hypertension is found.

Additional studies would include:

a. Early and late exposure during urography
b. Renal arterial angiograms
c. Angercamera-timed scintillation counter with programmed computer
d. Clearance studies
e. Howard's test, Rappoport test, and Stamey test
f. Angiotensin-infusion test (Kaplan)
g. Determination of renin-angiotensin as well as aldosterone assays
h. Electrolyte balance

Special consideration arises if hypertension is present together with urologic abnormalities but cannot be related to other causes.

Therapy

Renal Hypoplasia

Functional hypoplastic kidneys which do not produce symptoms, are free from chronic infection, and do not cause hypertension should be left alone. But as soon as hypertension develops, nephrectomy should be considered. The earlier this measure is instituted the more likely will hypertensive damage to the contralateral

kidney and secondary hypertension be prevented.

Arterial Defects

It is important to distinguish between intrarenal vascular changes and obstructions of the renal artery. In intrarenal angiomas, arteriovenous fistulas, renal infarcts due to emboli or thromboses, only partial resection of a kidney is needed. But defects of the renal artery without general destruction of renal parenchyma may be relieved by measures such as resection of the artery, arterial transplants, angioplasty, bypass or splenorenal anastomosis.

Although corrective vascular surgery, particularly the bypass, has not proven to be as satisfactory as had been assumed, it must be emphasized that an amelioration of arterial hypertension can be accomplished in many cases. Normotensive status can be reached in 50-60% of the cases; in another 10-20% a considerable improvement can be obtained.[1,10] Following is a typical case:

Case Report

Case 1

A 26-year-old male had stenosis of the right renal artery and poststenotic aneurysm with Recklinghausen's neurofibromatosis. His blood pressure, which was 210/120, was resistant to therapeutic measures. After resection of the stenosis and the aneurysm and end-to-end anastomosis to the aorta, the blood pressure dropped (Figure 1), followed by a secondary rise to preoperative values. However, after antihypertensive medication another drop occurred and the patient's blood pressure was permanently reduced.

*See Test Your Word Score, Page 1583.

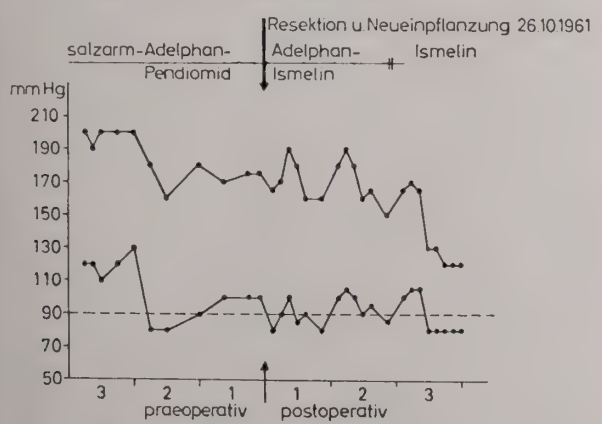

Fig. 1—26a Male (3002/61) Right renal artery stenosis. Preoperatively poor response to entire hypertensive therapy. Postoperative vacillations of blood pressure with final normalcy through administering ismelin.

Renal Cysts

With hereditary renal cysts as well as with unilateral polycystic kidneys the blood pressure is frequently elevated; in this series hypertension was found in 60% of cases. With the so-called polycystic kidneys, which by current concepts involve both organs, a diminution of the blood pressure may be expected only after surgical correction when one kidney is affected. The most valuable methods of surgical intervention are ignipuncture* to the small cysts or resection of the large as well as solitary cysts. Nephrectomy is contraindicated, since one may expect a cyst-predisposition even in the seemingly normal contralateral kidney. With conservative measures, which can result in amazing remissions and even with advanced loss of parenchyma, it has been possible to effect postoperative drops of blood pressure in practically all patients. It is difficult, of course, to differentiate the beneficial effect of surgery from the therapeutic value of treating the urinary tract infections usually found in these cases.

Hydronephrosis

Arterial hypertension was found in approximately 20% of 234 patients with hydronephrosis secondary to congenital ureteral stenosis. With the exception of far advanced destruction of renal parenchyma due to congenital hydronephrosis, where nephrectomy becomes mandatory, the therapy of choice is resection and plastic repair of the renal pelvis.[5,6,7,8] The indication to use this procedure may be quite liberally applied because of the kidney's regenerative ability. Following the establishment of normal urine excretion it may be expected that normal renal blood flow and decrease of the concomitant hypertension will occur. If the surgical repair fails to result in satisfactory renal function and relief of hypertension, a secondary nephrectomy may become necessary, after which one may observe final relief from hypertension.

Pyelonephritic Hypertension

In order to obtain benefit in a concomitant pyelonephritic hypertension it is mandatory to control the urinary pH by diet and medication, along with long-term antibiotic therapy and an

adequate "lavage of the urinary tract" by oral fluid intake as well as by instrumental irrigation in four-week intervals for the duration of one year. The following are cases in point:

Case 2

A 33-year-old male was admitted to the hospital with congenital left hydronephrosis. During two years prior to surgery progressive hypertension in spite of low Na-diet and at times antihypertensive medication. Plastic surgery of left renal pelvis on January 14, 1963. Routine postoperative care without antihypertensive therapy. A distinct reduction of hypertension ensued, although desirable diastolic pressures below 90 mm/Hg were not attained (Figure 2).

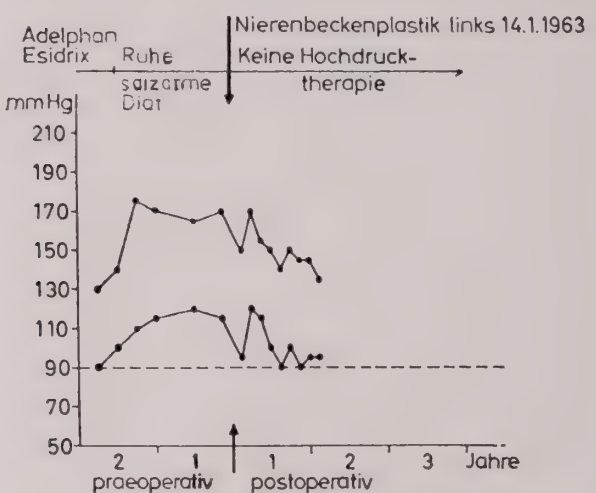

Fig. 2—33a Male (333/63) congenital mechanical hydro nephrosis on the left. Postoperative drop in blood pressure without antihypertensive medication. No return to completely normal.

Case 3

A 46-year-old female was admitted with congenital mechanical right hydronephrosis. During two years prior to surgery progressive arterial hypertension. Bedrest and low-Na diet lowered blood pressure even prior to surgery. Obvious drop in pressure after surgery to normal range for three years postoperatively. Then renewed if moderate hypertension, influenced favorably, however, by bedrest, low Na-diet and sedation (Figure 3).

Urinary Calculi of Ureters or Renal Pelvis

Arterial hypertension is associated relatively frequently with calculi of ureters and renal pelvis, particularly with complete obstruction of a ureter or calyx and complicating pyelonephritis. Sometimes there is an associated stenosis of the renal artery in cases of urinary tract calculi with concomitant hypertension, suggesting the need for an angiographic investigation wherever urinary tract calculi are associated with hypertension. The problem then arises whether, with removal of calculi, one should also correct vascular stenoses in order to have a favorable effect on hypertension and to prevent recurrence of calculi due to tissue anoxia. The following case demonstrates that it is possible to correct hypertension of long duration. Two years prior to admission this patient had been known to suffer from a ureteral calculus with complete ureteral obstruction and associated hypertension (Figure 4).

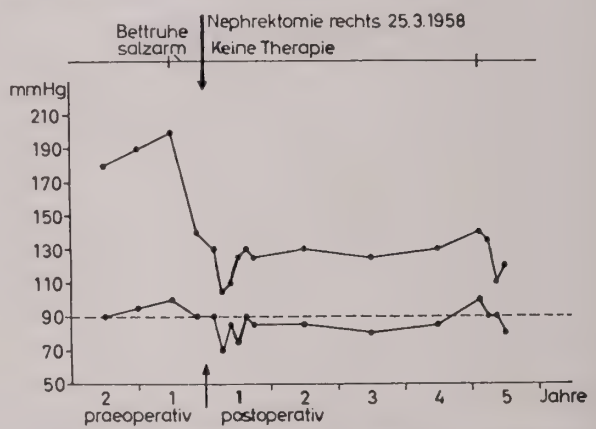

Fig. 3—46a Female (837/58) Congenital mechanical right hydronephrosis. Normal blood pressure after surgery. Recurrence after four years. Successful return to normal with antihypertensive therapy.

Fig. 4—Stenosis of the renal artery with calculus and pyelonephritis. Nephrectomy was done.

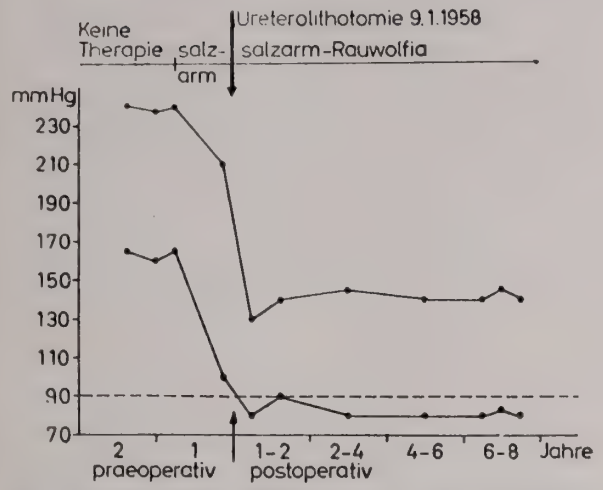

Fig. 5—54a Female (2957/57) Left ureteral calculus. Normal blood pressure after operation with antihypertensive therapy.

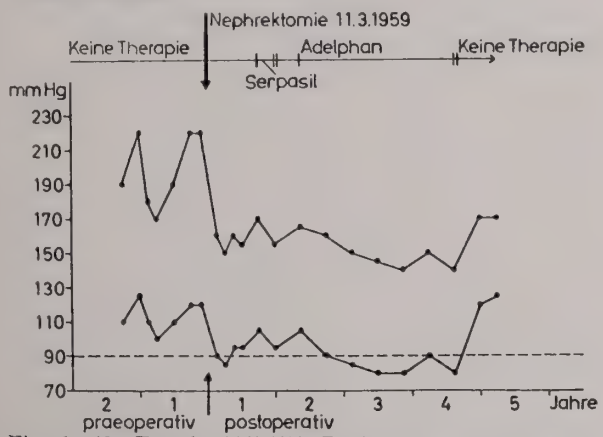

Fig. 6—43a Female (459/59) Pyelo-nephritic contracted kidney on the right, drop in the blood pressure after nephrectomy. Normal pressure with antihypertensive therapy. Resumed rise of blood pressure when therapy was omitted.

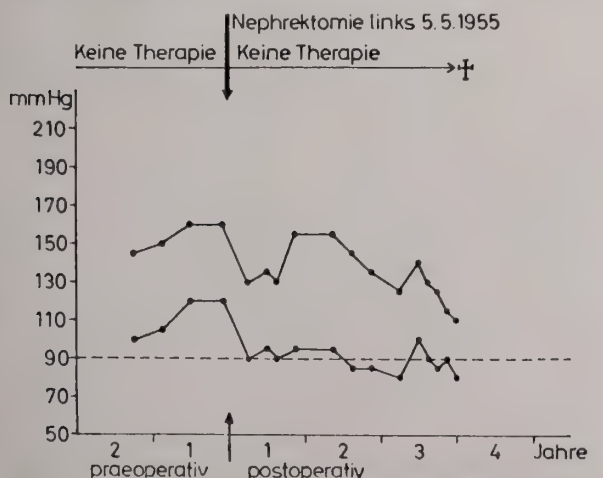

Fig. 7—54a Male (47/58). Left hypernephroma. Died of multiple metastases in 1960. Postoperative drop of blood pressure. Without antihypertensive therapy there occurred a rise in the third year after surgery. Another drop of blood pressure with tumor petechia.

Case 4

A 54-year-old female, occluding left ureteral calculus. Hypertension for two years prior to surgery. Low Na-diet and bedrest had resulted in only moderate improvement. Blood pressure became normal however, after ureterolithotomy, subsequent low Na-diet and Rauwolfia therapy (Figure 5).

Contracted Kidneys

In contracted kidneys, due to inflammation or calculi followed by inflammation, nephrectomy is the only reasonable solution and usually leads to normotensive states if hypertension has not been present for too long a time (Figure 6).

Patients with contracted kidneys have a better prognosis concerning postoperative blood pressure than those with other renal diseases, as stated previously by Braasch, Pickering and Heptinstall, Thompson, Gifford and von Niederhäusern and Wildbolz.

Tumors of Kidneys and Renal Pelvis

We also observed arterial hypertension in tumors of the kidney and renal pelvis, where nephrectomy is indicated on principle. Forty-one (17.4%) of 247 such cases had associated hypertension. Nephrectomy may be regarded as curative therapy for this type of hypertension, considering that 16 of the 22 patients who were followed after surgery showed a material drop in blood pressure (Figure 7).

Although in these cases the survival of patients is determined by the course of the malignancy, a curtailment of life expectancy due to hypertension can be avoided; but such a shortened survival may occur and lead to death if the tumor is treated solely by irradiation.

Prognosis

Extensive follow-ups on our patients showed that one can expect a fall in blood pressure in 30 to 60% of the cases. On the other hand, one may also anticipate renewed rise of blood pressure within two years following surgery in 25 to 30%. This appears to be the case particularly in hypertension of long duration in which the postoperative blood pressure is not observed closely and rising pressures are not treated promptly by antihypertensive therapy. The well-planned, long-term antibiotic therapy of an existing urinary tract infection is equally

important in order to avoid postoperative rise of blood pressure. In the case of renovascular hypertension immediate antihypertensive postoperative treatment is mandatory. It is significant that hypertension which was resistant to therapy before operation will respond to such therapy postoperatively.[3,8,9]

Based on our recent experiences there is assurance that the prognosis of renal hypertension can be further improved, if therapy is not limited to surgery alone but includes postoperative controls and, if necessary, long-term antihypertensive and antibiotic treatment. Leishman's findings indicate the importance of a lowered blood pressure, even if only moderate. He found that decline of the diastolic pressure by 10 to 30 mm/Hg increased the survival time of hypertensive patients from 1/6 to 1/3.

Interpretive Fallibility

Of recent years the powers that be in the profession have made it quite impossible for one to take a firm stand in an opinion unless backed by a blood chemistry analysis, cardiograph, gastrointestinal barium meal and enema, fluoroscopy, gastric content examination, and needling. These are invaluable gadgets to eliminate doubt or settle argument, but used indiscriminately and as a matter of routine they destroy faith in one's ability to reach a satisfactory conclusion. . . . And the interpretation of graphs, X rays, and charts is still subject to the frailty of human inaccuracy and indecision.

I have watched genitourinary specialists operate for a kidney stone to find that the shadow on the X-ray plate was a gallstone. I have been in consultation with heart specialists whose findings indicated coronary occlusions, when in reality the gall bladder was the seat of the disease, and not the heart. I have heard radiologists claim the presence of an ulcer of the stomach when an operation revealed its absence. I operated upon a subphrenic abscess demonstrated by an X-ray expert and found nothing. I was almost persuaded once by an eminent pathologist to remove a young female's entire generative organs for cancer when none existed, because of the microscopical findings; the woman still lives fifteen years later, without mutilation. I have seen normal gall bladders explored because the interpretation of the pictures was misunderstood. I could go on indefinitely reciting proofs that the machines are not foolproof.*

Preservation of Kidney and Liver Transplants

K. J. PAQUET, M.D.*
J. CERNY, M.D.†
Bonn, West Germany

THE PRESENT TECHNIQUE of organ preservation extends the ischemia tolerance time to several hours. This time interval, however, does not allow for transportation of the organ to the transplantation center, mobilization of the surgical team, preparation of the recipient, and performance of histocompatibility tests. It is thus urgently necessary to develop methods of prolonged organ preservation and to establish an organ bank, similar to a blood bank, in which organs are available at any time.

Preservation Principles

Hypothermia

Hypothermia reduces metabolic activity, lowers oxygen requirements, and decreases metabolic waste products. The O_2 consumption of the tissues diminishes exponentially‡ with falling temperatures, thus prolonging the ischemia tolerance. Hypothermia can be employed in different ways:

1. Cooling to temperatures slightly above 0°C.
2. Cooling below 0°C. without freezing
3. Freezing

While cooling below 0°C. reduces metabolism markedly and freezing results in a virtually complete cessation of metabolism, the usefulness of cooling to 2-4°C. is restricted to only a few hours.

Hyperbaric Oxygenation

High pressure intensifies molecular motion. Diffusion of oxygen into the tissue and of carbon dioxide out of the tissue is accelerated by high pressure. Because the number of diffusible particles is proportional to the partial gas pressure, employment of pure oxygen increases the effect of this procedure, depending on the organ thickness and the pressure applied. Because of an organ-specific sensitivity

†Fellow of the A. von-Humboldt Foundation, Bad Godesberg, Germany.

‡See Test Your Word Score, Page 1583.

to hyperbaric oxygenation, however, there is a practical limit for the use of high oxygen pressures.

Metabolic Inhibition

The drug-induced reversible enzyme-inhibition resulting in a reduced metabolism is a distinct aid in organ preservation; it prolongs the ischemia tolerance considerably. Phenothiazines, for example, inhibit enzymes[56]. Perfusion with reversible metabolic inhibitors, such as magnesium-sulfate, Adenochrome or sodium fluoride results in prolonged survival of various organs up to six hours[43]; but this method has advantages over simple hypothermia only in combination with other methods of organ preservation.

Continuous Perfusion

Organ perfusion by means of a pump-oxygenator has gained importance. Ideally it produces a continuous blood circulation in the organ, providing for a steady and adequate elimination of carbon dioxide and metabolic waste products as well as for a continuous supply of oxygen and energy. The most important precondition for a successful procedure, besides the oxygenator and pump, is a satisfactory perfusate. The efficiency of this method is limited, however, because of our inability to reproduce the physiological conditions exactly and completely.

Hypothermic perfusion permits the use of erythrocyte-poor or -free fluids, thus reducing or eliminating damage or destruction of erythrocytes by the pump. Perfusion pressures, which can produce severe organ damage even at so-called normal levels may be decreased[2,98]. In hypothermia using a pressure of 10 mm. Hg., an organ perfusion with 2-4 ml/minute and with a perfusate of 50% blood and 50% balanced, buffered electrolyte solution and low molecular weight dextran, or with albumin and heparin, results in a good organ conservation for up to 48 hours[2,98].

The effectiveness of a preservation method can be best ascertained by function tests after the transplantation, when irreversible ischemic damage and secondary circulatory damage is to be excluded. Function tests during the preservation are informative only when the employed technique—as in hypothermia—does not result in a reduction of the metabolism. The vitality of an organ may be evaluated by determining its adenosine triphosphate-reserve, the metabolic products of anaerobic glycolysis and the activity of various enzyme systems[9,46]. Important morphologic changes can be detected through electron microscopic and histologic studies in all phases of conservation[103,111,112]. A relatively reliable criterion is the avoidance of weight gain of the organ and maintenance of a stable pH-value.

The Kidney

The ischemia tolerance of the normothermic human kidney is quoted as varying between 90 and 120 minutes. After 60 minutes an impaired kidney function appears; 90 minutes of ischemia result in severe tubular damage, and after 120 minutes the damage becomes irreversible. The following methods of kidney preservation have gained practical importance:

Normothermic perfusion

a. By gravity
b. By oxygenator-pump-system

In contrast to kidney perfusion with an oxygenator-pump-system the normothermic gravity perfusion has gained little importance. The perfusion apparatus and the composition of the perfusate are designed to create physiological conditions, providing adequate circulation, oxygenation and nutrition of the kidney graft. Blood is the preferred perfusate since the oxygen capacity of red-cell-free solutions is inadequate at normal temperatures. Diluted blood is hemodynamically superior to undiluted blood. Telander recommends 200 ml. of fresh heparinized blood to which 100 ml. physiologic electrolyte solution and 50 ml. low molecular dextran are added. The urine output must be balanced by continuous replacement with electrolyte solutions. By combining perfusion dialysis and perfusion, the ischemia tolerance can be prolonged[43,85].

Figure 1 shows Paquet's apparatus consisting of an organ container, oxygenator and pump. Others have described modifications[7,8,18,21,37,38,43,85,87,94,95]. Pig kidneys perfused with pulsatile flow survived about 12 hours[67,68,72]. The urine output was 4 ml/minute at blood

flows of 150-300 ml/minute. A better and longer continuation of kidney function was obtained only by maintaining pulsatile flow rather than non-pulsatile perfusion[68,72]. Telander maintained sheep and baboon kidneys in a functional state up to 24 hours; but only those kidneys that were grafted within seven hours after harvesting resumed function[94,95]. The advantage of this perfusion procedure is physiological preservation; its disadvantage is the large apparatus required. At times an uncontrollable rise of pressure occurs in the perfusion system, resulting in vascular damage and extravasation followed by decreased kidney perfusion and oliguria[39,69,70,103,112].

Hypothermia

a. Osmodiuresis—preservation-hypothermia

b. Combination of gravity-perfusion and hypothermic osmodiuresis

c. Combination of gravity-perfusion hypothermia osmodiuresis, and hyperbaric oxygenation

d. Perfusion hypothermia (gravity, low-flow, mechanical)

e. Combination low-flow-perfusion, hypothermia and hyperbaric oxygenation

Many experimental investigations have shown the protective mechanism of hypothermia against ischemic kidney damage;[3,4,11,16,18,20,21,29,44,64,78,79,80,83,84,93,96,97,100,101,105,110,114] its clinical value has been demonstrated in many human kidney transplantations[5,13,16,22,32,45,59,88,89,92]. It has been demonstrated on the dog kidney that there is a logarithmic relationship between temperature and oxygen consumption; the O_2-consumption of 100 gm. kidney at zero° C. is reduced to 0.075 ml/minute[52].

The cooling of kidneys to 2°-4° centigrade combined with other preservation methods has proven superior experimentally and clinically[2,55,98]. Therefore we shall omit mention of the many experiments with hypothermia combined with the use of antifreeze substances and with freezing alone[15,17,24,75,77,83,84].

In the *osmodiuresis-hypothermia method* of

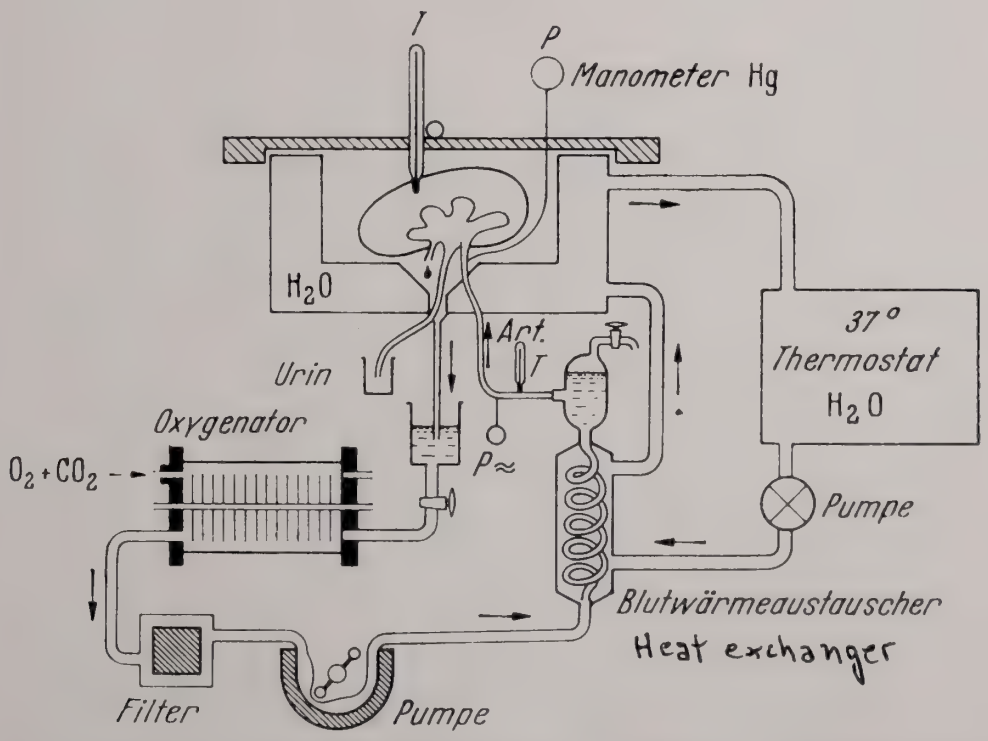

Fig. 1—Perfusion system for isolated kidneys (after K. J. Paquet et al., Langanbeck's Arch Klin Chir 304:735, 1963.

organ preservation the donor receives 250 ml. of a 20% mannitol solution* intravenously prior to nephrectomy. The excised kidney after drainage of blood is placed in a plastic bag. It is then cooled and stored in a thermo-apparatus (Figure 2) charged with a coolant. During the vascular anastomosis and after releasing the circulation to the transplant the recipient receives also 250 ml. of a 20% mannitol solution[101,104]. With the use of this method for periods of up to six hours Vahlensieck et al. observed in patients an immediate postoperative resumption of function[101,104].

Histologic and particularly histometric investigations[103,112] led us to use the combination of hypothermic osmodiuresis with an initial hypothermic gravity perfusion of five to 10 minutes. We have found a solution† developed by Largiader most suitable:

A.

Basic Solution

Sodium	140 mEq/liter
Potassium	7 " /liter
Calcium	5 " /liter
Magnesium	3 " /liter
Chlorine	105 " /liter
Lactate	50 " /liter
Glucose	2.0 gm/liter
Albumin	12.0 " /liter
Mannitol	0.5 " /liter

B.

Supplementary Solution

Tris buffer 0.3 molar	1.25 ml.
Sodium bicarbonate	4.8 mEq.
Procain hydrochloride	0.5 gm.

pH 7.25 to 7.38 at 6°C.; osmolarity 320 mos/ml.; 50 mg/liter of heparin (pH 5.5) are added and the pH is adjusted to the value listed

*Osmofundin, Braun, McLspurgan.
†Perfusions lösung, Dr. Frensenius, Bad Homburg, v.d.h.

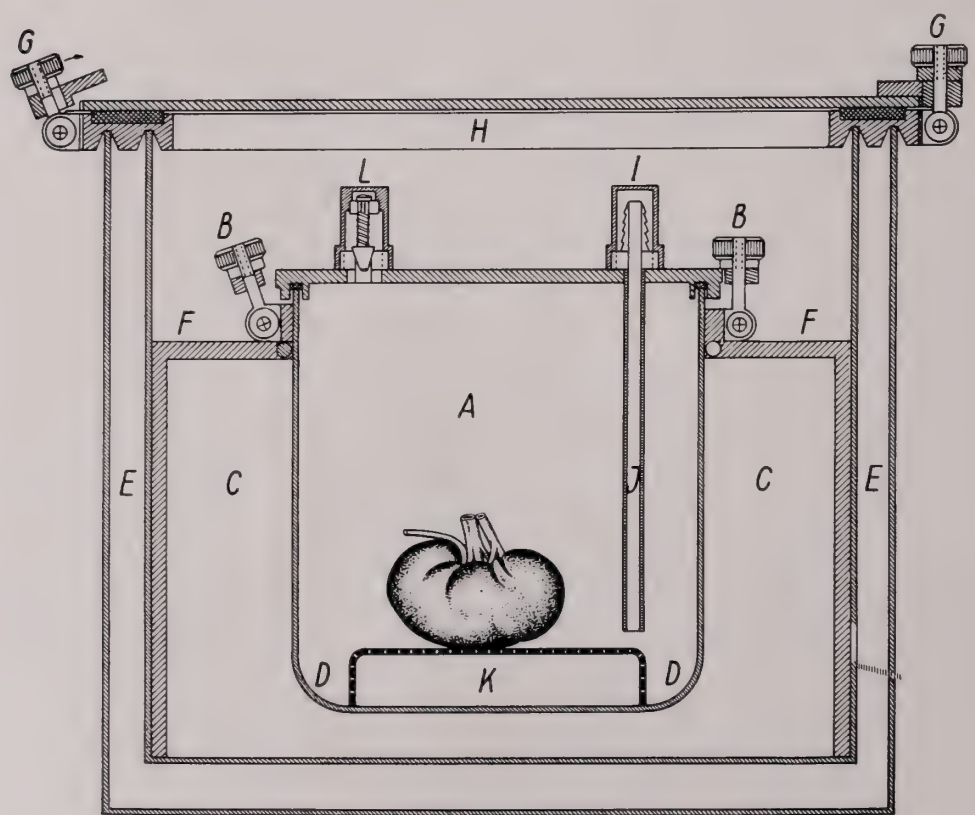

Fig. 2—Container for transplant preservation under hypothermia and with hyperbaric oxygenation (after W. Vahlensieck: Vhdl Dtsch Ges Urol, 1965. Springer-Verlag, Berlin-Gottingen-Heidelberg, 1966.)

above. The addition of other medications such as Complamin*, Euphyllin†, Intensain‡, Papavarin hydrochloride or Persantin§ serves to protect the organ additionally[23,39,62,67,69,70,72,109].

Simultaneous hyperbaric oxygenation and hypothermia prolong the ischemia tolerance (Figure 2) to 24 hours[35,37,51,54,57,101]. Fresh cadaver kidneys preserved for eight to 12 hours by this method resumed their function after transplantation[47,49,54,58].

In another series of experiments we preserved dog kidneys by *gravity perfusion* with the same perfusate at 4°C. for up to 80 hours. Oxygenation was, in our opinion, not necessary because of the reduction of oxygen requirements to 5% at this temperature. The results indicate that with this method of preservation an ischemia tolerance of up to 48 hours can be obtained[113].

The same result was obtained with the *low-flow-perfusion* (perfusion pressure 10 mm.Hg., kidney flow 2-4 ml/minute) and a perfusate of 50% blood and 50% balanced buffered electrolyte solution with addition of low molecular dextran or albumin and heparin, respectively[30,55].

For *machine-driven perfusion-hypothermia* the same apparatus used for the normothermic perfusion can be employed, if the blood heat exchanger is replaced by a blood cold exchanger. The perfusate consists of about 50% blood, Ringer's solution, low molecular dextran, bicarbonate, a buffer substance, heparin and procain with the pH adjusted between 7.25 and 7.40. At temperatures below 10°C. the arterial pressure should not rise above 50 mm.Hg.

A combination of *low-flow-perfusion, hypothermia and hyperbaric oxygenation* has recently been shown to produce the longest renal ischemia tolerance—in some experiments up to 72 hours[2,98].

The Liver

The ischemia tolerance of the liver is less than that of other organs; the occlusion of the afferent liver vessels is tolerated for only 20 minutes. The resultant parenchymal damage becomes irreversible after 30 minutes[74].

The pig liver with a longer ischemia tolerance time is an exception. Thirty minutes after the pig's death, and under normothermic

§Dr. Thomae, Biberach a.d.R.

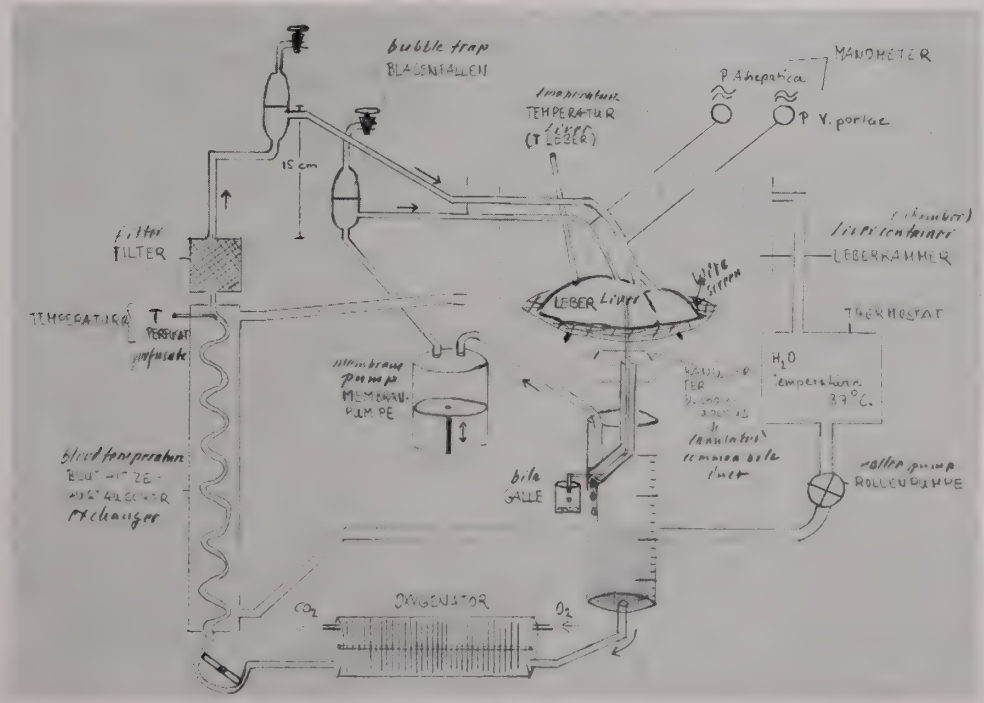

Fig. 3. Apparatus for perfusion of an isolated liver.

conditions, the liver resumed normal function with isolated perfusion[106,108].

It is possible, however, to increase the hepatic ischemia tolerance when hypothermia and perfusion by gravity are started in vivo[14,26,28,33,40-42,66,76,86,108], as also shown by our investigations[71]. We therefore recommend cooling of the liver before transaction or tying of the vessels.

Hypothermia and Hyperbaric Oxygenation

We have discontinued the use of simple hypothermia without perfusion in favor of a brief hypothermic gravity perfusion at 4°C. and subsequent storage in the refrigerator. The perfusate consists of Ringer's lactate solution with added albumin, low molecular dextran, glucose (as nutrient), a buffer and heparin. However, the efficiency of this method is limited[41,42,55,86,108].

Cooling below the freezing point, but without ice crystal formation, by using hydrostatic pressure or addition of dimethyl sulfoxide failed to prolong appreciably the ischemia tolerance of the liver. A partial success was obtained by dehydration of the liver by about 15% of its volume, at 2°C., and preservation of the organ by immersion in glycerol or dimethyl sulfoxide (-6°C.). In-vivo tests after heterotopic transplantation showed a limited function up to four days[10,14,50]. Organ preservation by freezing, however, has failed; in spite of protective measures taken, freezing damage has occurred.

Storage of the gravity-perfusion-cooled organs in a closed container, charged with oxygen under high pressure, increases the ischemia tolerance[14,33,35,41,42,54,57,58,86]. The effectiveness of this method depends upon the organ thickness and the applied pressure and is less in the liver than in other organs.

Perfusion

The reestablishment of the function in a transplanted liver which was preserved for more than six hours by normothermic perfusion has as yet not been reported. It is presumed that the organs were cooled before and after perfusion[6,26,27,33,53,61,66,76,86,91]. Our own dog experiments also failed to exceed this time limit[71]. We cannulated the hepatic artery and portal vein; the hepatic vein was allowed to drain. The perfusion system had two power sources. The hepatic artery perfusion was kept pulsatile by pump at 100/70 mm.Hg. pressure. For the perfusion by gravity of the portal vein the perfusate was elevated 15 to 20 cm. above the liver. The perfusion system was completed by the addition of an oxygenator, a heat-exchanger, two thermometers, two manometers, two bubble traps, a filter and a reservoir which could be used as a flow meter. The connecting parts were made from siliconized Tygon tubing. The bile flow was diverted and the amount replaced. The organ container was made from V-2a-Steel (stainless steel-Ed.) with an inner and outer thermo-insulating coat. A device was attached for introducing hyperbaric oxygen (Figure 3). Similar chambers have been described by others[28,34,42,66,76,86].

In the center of the slanted container bottom was the outflow spout for blood from the hepatic vein and for the bile drainage catheter which was inserted in the common bile duct. The inlets for the hepatic artery and portal vein were located on the lateral wall of the organ container. Both cannulae were connected to a manometer. The liver rested on a fine wire screen. Prior to hepatectomy the hepatic artery and portal vein were cannulated. After ligation of these structures they were perfused by gravity with low molecular dextran and sodium bicarbonate at 4°. A cholecystectomy was done and the common bile duct was cannulated. Eight to 10 minutes were needed for connection with the perfusion system. Gravity perfusion was continued during this time. The solution used in the extracorporeal liver perfusion with the oxygenator-pump consisted of 50% autologous blood, 20-30% Ringer's lactate, 10-15% low molecular dextran, sodium bicarbonate and heparin. The amount of bile produced during the six-hour perfusion varied between two and 10 ml/hour.

Hypothermic perfusion, particularly in combination with hyperbaric oxygenation, results in an additional prolongation of the ischemia tolerance time. The perfusate should contain not more than 50% blood, and the perfusion pressure should be stabilized below the physiological level[12,42,55,98]. The continuation—or the beginning—of the hypothermic extracorporeal circulation after death is a similar method of liver preservation. This was done for the first

time on heart surgery patients who could not be resuscitated[47,60,61,63,90]. To this day all human liver transplants have been preserved by this method. The longest period of ischemia was eight and one-half hours and the transplant functioned for several days[1,90]. By the combination of hypothermia, addition of metabolic suppressants, hyperbaric oxygenation and low-flow perfusion it was possible to increase the ischemia tolerance time of the liver from 48 to 72 hours[12,55,98].

Translated by: Emil Schleicher, Ph.D.

Summary

The various methods of organ preservation for transplantation are described. Our experimental and clinical experience with the preservation of kidney and liver is compared with reports from others. The limitations of the individual methods of preservation and their potential for improvement are discussed. In animal experiments the kidney and liver preservation was extended from 48 to 72 hours.

Does Education Pay

Does education pay? What a question!

Does it pay to prepare the ground before sowing the seed?

Does it pay to polish the precious stone before putting it on the market?

Does it pay to plane and sandpaper the board before putting it into the piece of furniture?

Does it pay to sharpen the tools before working with them?

Does it pay to know things rather than live in ignorance?

Does it pay to have a mind rather than be a mere animal, and be directed by those who have minds?

Does it pay to think, and if so, to think with a trained mind rather than with an untrained one?

Does it pay to be a leader rather than a follower?

Does it pay to make the most of the faculties God has endowed one with, or to let them lie dormant?

Does it pay to be one of the capable of the human race or to be one of the inferior?

Does it pay to prepare oneself to do large things or to remain satisfied to do small things, and let others take the advanced positions?

Does it pay to take advantage of opportunity and make the most possible of oneself?

Does it pay to get an education? Only the lazy and the ignorant answer, "No."

Pay? Surely it pays—manyfold. There can be no better investment nor one anywhere near as good.

Let no youth be deceived. Ask those who are educated. Ask the wise of any generation. Be sensible. Get the education while you have the chance. Prepare to live a happy and prosperous life.

—Ward H. Nye, Superintendent of Schools, Billings, Montana.

Doctor

I remember when I grew up in the little town of Woodville, just north of Beaumont in the pine woods of eastern Texas, when we needed a doctor for a member of the family, we called Dr. So-and-So. If a cow was sick or one of the horses or even a pig, we usually called the same doctor.

But now when you go to see your family physician, you probably will wind up having a specialist recommended to you. A friend of mine did that, in this changing world, a few days ago, and the specialist recommended was a skin specialist. And he went over to the specialist who said, "Let me see your hands."

And he looked at them and said, "Yes, yes, yes, I see. Have you ever had that before?"

And the man said, "Yes."

And the specialist said, "Well, you've got it again."*

Importance of Early Diagnosis of Renal Tumors

W. VAHLENSIECK, M.D.*
ST. GÖDDE, M.D.*
Bonn, West Germany

WITH THE DEFINITELY increasing incidence of malignancies[1] the frequency of renal tumors is also observed. Early diagnosis is very important for a favorable prognosis especially because curative radical surgery is superior to cytotoxic substances and radiation therapy. It is important to recognize the early symptoms of renal tumor; whenever any doubt exists, it is better to undergo extensive testing rather than wait for a definite sign, because the tumor may then have reached an incurable stage.

Our observation of 204 histologically verified tumors of the kidney, correlated with a careful study of case histories, showed that early symptoms were sometimes neglected by the patient or the doctor; or because of being nonspecific they were misinterpreted in favor of the overemphasized "cardinal symptoms:" gross hematuria, pain, and a palpable mass. These signs are late and may not always be found in patients with parenchymal tumors of the kidney. In our study gross hematuria was found in 49.6% of cases of advanced hypernephroma.[6] From the data of other authors gross hematuria does not occur in half of all the renal cases.[11,10,16]

Late Signs and Symptoms

Absence of Hematuria

Causes for late occurrence or complete absence of gross hematuria in renal tumors have been collected and recorded[6]:

1. Causes in tumor itself or surrounding the tumor (Figure 1):
   a. Peripheral localization of the tumor with centrifugal expansion
   b. Central localization, having capsule that prohibits expansion and infiltration
   c. Growth within a cyst
2. Extrarenal causes (Figure 2):
   a. Congenital or acquired stenosis of the ureter

*Surgical Clinic, University of Bonn, Department of Urology. Director: Professor A. Gütgemann, M.D.

b. Obstruction of ureter by blood clots, particles of tumor or calculi
c. Occlusion of lower urinary tract due to obstruction or combination of obstruction plus stenoses.

Dysuria

Dysuria, which would guide the patient to a urologic examination and diagnosis, occurs rather infrequently.

Absence of a Mass

In cases where gross hematuria is missing due to peripheral localization of the tumor or due to the development of a tumor in a fibrous-inflammatory capsule or in a cyst, the tumor may have a tendency to slower growth and be impalpable because of the inhibiting capsule.

Contrary to carcinoma of the thyroid or of the breast, renal tumors are not noticed by the patient in their early stages, due to their anatomical position or because of obesity; though in patients who are not obese and providing that the abdominal wall is completely relaxed, smaller renal tumors may be detected by bimanual palpation. Without hesitation a "palpable mass" should be considered as a late sign of tumor.

Pain

Pain as a symptom in renal tumors is not a constant complaint and was missing in 22% of all cases analyzed. It is understandable when we remember that pressure pain or neuralgic-like complaints start only when the tumor has grown large enough to cause increased pressure in the calices, increased tension of the renal capsule, or pressure on surrounding organs; or when it has metastasized to lymph nodes or to the spine. Episodes of renal colic may be observed due to the passage of blood clots or particles of tumor tissue.

Other late signs giving clue to the diagnosis in our series[7] were spontaneous fractures due to metastases to the bone, hemoptysis due to lung metastases, varicocele in 11%, anemia in 40% of the cases, leukocytosis with shift to the left, and polyglobulinemia in 2 to 5% of the cases.

Early Signs and Symptoms

The question arises: are there really any early signs and symptoms that would prove significant enough to include them in the general examination of a patient?

Fever of Unknown Origin

Perhaps one of the earliest signs is a low-grade intermittent fever associated with absence of leukocytosis. Elevation of temperature is caused by seepage of tumor protein or protein metabolites into the blood stream.

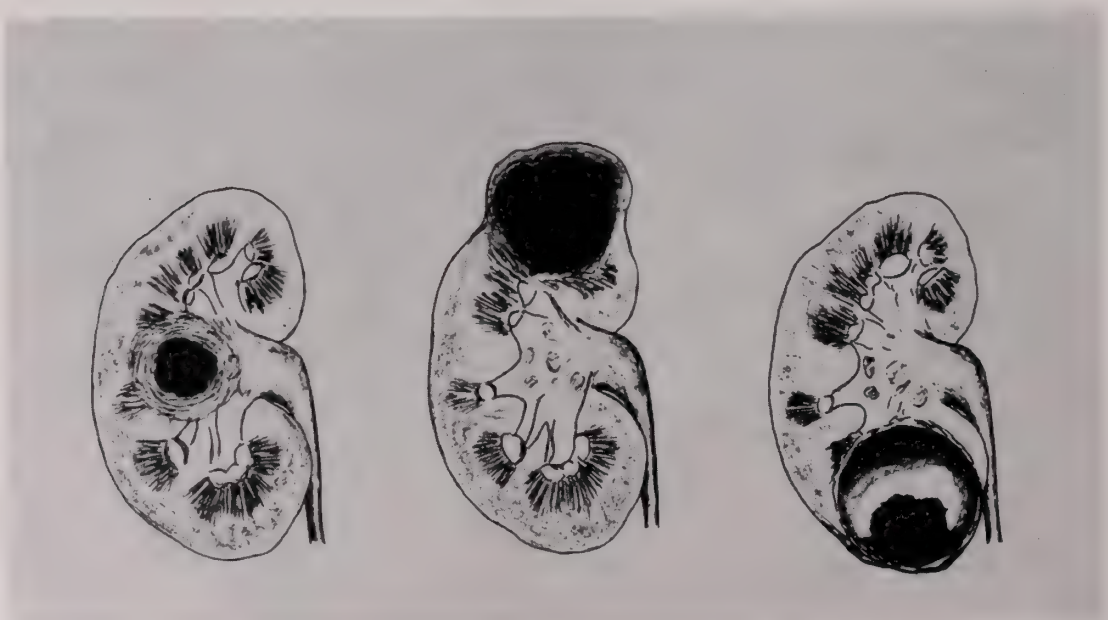

Fig. 1—Localization of tumors causing no gross hematuria.

Other causes may be associated with pyelonephritis or cystitis accompanied by typical pain or dysuria, which should aid in the differentiation. The incidence of early intermittent elevation of temperature occurred in 12 to 30% of cases. In our series the incidence was 12%. In several cases low-grade intermittent fever was the only symptom of a renal tumor. Other authors agree that the elevation of temperature ceases after nephrectomy.[2,14]

Gastrointestinal Complaints

If gastrointestinal complaints cannot be explained by tests, the diagnosis of renal tumor should be considered; in this series six patients had prolonged testing, treatment and observation for gastrointestinal complaints before diagnosis of renal tumor was made. This is a low percentage and possibly coincidental, as these complaints are difficult to explain on the basis of renal tumor. However, they should be considered when discussing the early diagnosis of renal tumors.

Diastolic Blood Pressure

Elevation of the diastolic blood pressure due to some renal factor is found more often.[8] In this and other[12] series marked elevation of blood pressure was found in approximately 22% of cases. In patients with Wilms' tumor diastolic pressure was found to be elevated in 50 to 75% of the cases.[3,9,13] It should be considered an important sign and an early symptom for the diagnosis of renal tumor.[15]

Microhematuria

As a rule, in all cases of malignant renal tumors grossly clear urine shows early microhematuria. Evans, Riches et al. and Staehler found erythrocytes in the urine in 80 to 100% of cases. Even in early stages it is demonstrated by repeated examination.

In our series microhematuria was demonstrated in 87% of the cases. It is due to stasis of venous blood resulting from compression of the parenchyma by tumor and by local inflammatory changes and secondary infection in the renal pelvis.

Elevated Sedimentation Rate

In our series the elevated blood sedimentation rate was found to be a very significant and important clue for the diagnosis of renal tumor; in almost all cases elevation of the blood sedimentation rate was demonstrated in one- and two-hour readings. In these cases renal tumors were always considered, especially if elevation of the blood sedimentation rate could not be otherwise explained. Though this is a nonspecific test, the difficulty of ruling out other causes and seeing most of our patients in the late stages of renal disease, we consider an elevation of the blood sedimentation rate an indication for thorough and complete investigation for renal tumor if no other explanation can be found.

Comments

From these facts it can be concluded that the early symptoms are very few and nonspecific; however, early diagnosis and a favorable prognosis can be achieved only by observing these early signs and pursuing them with specific diagnostic tests. Technically well performed x-rays of the kidneys will frequently

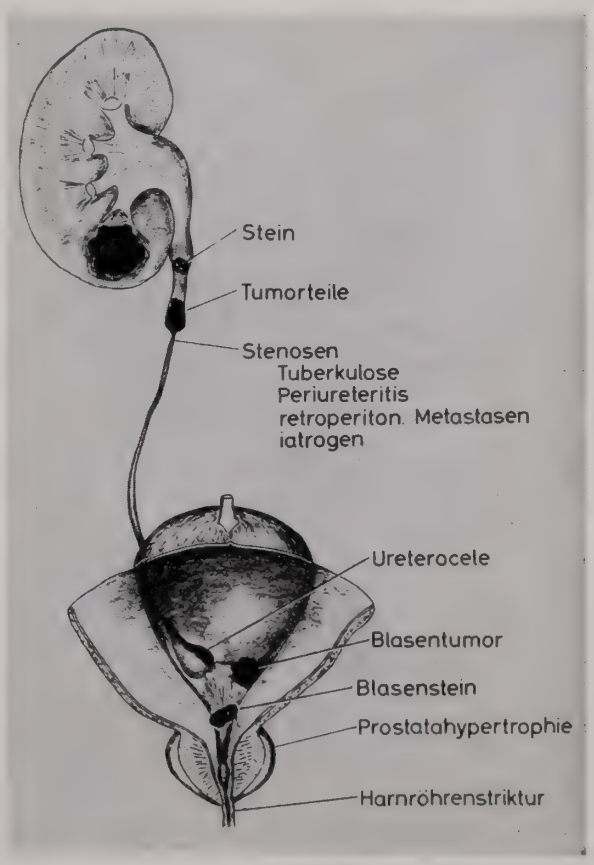

Fig. 2—Extra-renal causes for absence of gross hematuria: obstructing calculus, tumor tissue, stenosis, ureterocele, bladder tumor, bladder stone, prostatic hypertrophy, and stricture of urethra.

detect even the peripheral tumors by showing a distortion of the renal outline. As a rule small renal tumors may be demonstrated by large doses of intravenous contrast media, infusion pyelograms, tomograms or rate films.

In cases of doubt, renal scan may help the diagnosis, causing an insignificant amount of radiation. If even then doubt persists, retrograde pyelography and especially angiography is indicated.

Even if it is not always possible to differentiate between a cyst and a renal tumor, at least decision can be reached if surgery is indicated and an important step from early recognition to early treatment and better prognosis is made.

Conclusions

After observing 204 cases of parenchymal renal tumors with verified histological findings, conclusion is made that so-called *cardinal symptoms* — gross hematuria, pain, palpable mass, complaints caused by metastases, varicocele, anemia, leukocytosis with shift to the left, symptomatic polyglobulinemia—are observed in late stages. Statistics show that gross hematuria, due to tumor itself or surrounding causes or extra-renal causes, can be expected in only 50% of cases, and pain in only 22% of cases. Attention should be devoted to early signs like puzzling, intermittent fever (12-30%), unexplained gastrointestinal complaints, elevation of blood pressure (20-75%), microscopic hematuria (80-100%) and otherwise unexplained elevation of blood sedimentation rate.

If these symptoms cannot be explained by other means, special tests for renal tumor are indicated. By different diagnostic procedures, not significantly affecting the patient, early diagnosis should be achieved, leading to early treatment and a better prognosis.

Experimental Perfusion of the Pancreas

N. DRAZNIN, M.D.*
A. BLOMER, M.D.*
R. SCHOLZ*
H. SEBOLDT*
Bonn, West Germany

IN TRANSPLANTATION of the pancreas, as in other organ transplantations, it is necessary to perfuse the excised organ during the ischemic phase. The proper composition and temperature of the perfusate prevent damage to the organ graft.

The pancreas poses particular problems due to the liberation of enzymes during operative manipulation, followed by autolysis.

The commonly used pancreas perfusate is dextran with added heparin. Glucose and procain adjusted to a pH of 7.4 is sometimes added[4] or small amounts of Trasylol[5]. Others do not use perfusation[1] but inject heparin solution into the vessels of the graft after transection.

The prevention of autolysis by the use of an enzyme-inhibitor during the operation and during perfusion of the excised organ is the principal problem, since acute pancreatitis may occur after manipulation and ischemia of the

organ. Greep[3] has shown that enzyme-inhibitors work best if administered before the pancreas is damaged. Once damage has occurred the efficacy of the enzyme-inhibitors diminishes in proportion to the time elapsed prior to its utilization.

Procedure

One hundred thousand units of Trasylol diluted in 250 milliliters of Rheomacrodex is injected into the donor animal during the operation. Immediately prior to excision of the organ the animals are heparinized with 5,000 International Units, in order to avoid clotting of the pancreatic vessels after transection. This method seems to be superior to the customary heparin perfusion after excision of the organ; with the latter method we have observed clotting in several instances.

Immediately after excision the pancreas is perfused through the celiac axis with a special solution:

Since the normally functioning pancreas metabolizes proteins we use an amino acid stock solution and add to each liter of 400,000 units Trasylol, 50 grams dextran, 10 ml Complamin and sodium bicarbonate in sufficient amounts to adjust the pH value to 7.35-7.40. The dextran aids the intravascular fluid retention and the Complamin prevents vasoconstriction. Only fresh solutions should be used, since they tend to become alkaline within three hours, at room as well as in cold temperatures.

We use gravity perfusion with a pressure of 120 centimeters water. The perfusion apparatus is shown in Figure 1. Its construction provides for a perfusate temperature of 2 to 6 degrees C; within these limits the temperature varies with the inflow volume. We found that a flow volume of 75 ml/min corresponds predictably to a temperature of 4 degrees C at the outlet. This flow volume proved to be optimal for a pancreas of dogs

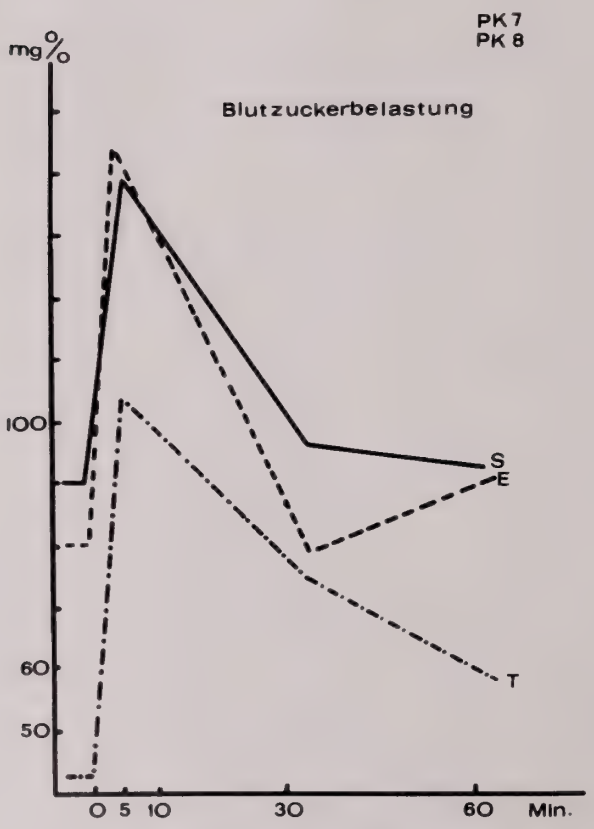

Fig. 2—Blood sugar tolerance curve after intravenous injection of 3 gr. dextrose in donor and recipient dogs, fasting.

——— S = Donor dog before operation; ···· E = Recipient before transplantation; -.-.-.- T = Transplanted pancreas six days after the operation.

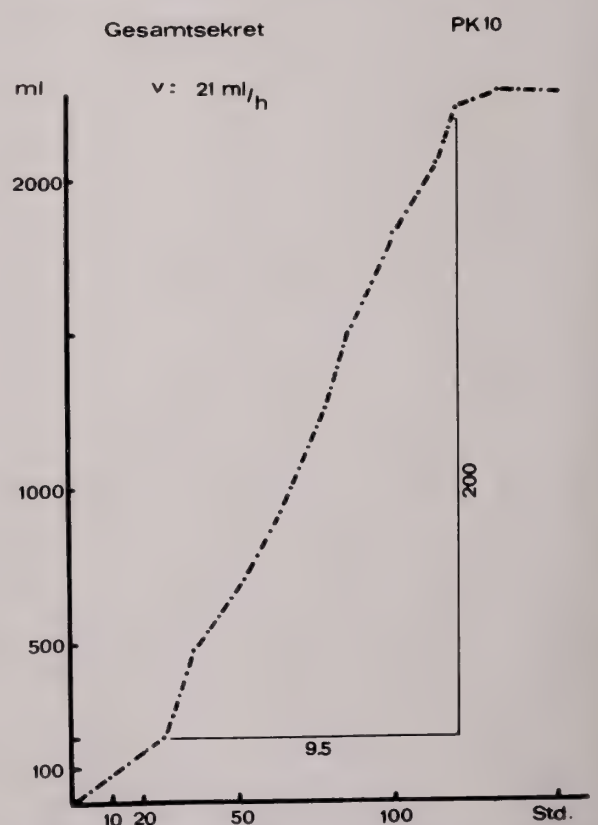

Fig. 3—Total secretion of the transplanted pancreas 130 hours after the operation.

weighing from 15 to 20 kilograms. When the flow is increased one occasionally sees tissue infiltration. In these instances, however, we found no evidence of impaired pancreatic function as compared with transplants which have undergone perfusion with lower volumes.

Results

Numerous determinations of intracellular sodium and potassium content in pancreatic tissue were made both before and after perfusion. We found no significant differences; there was also no change in O_2-consumption.

The grafts which did not receive immunosuppressive therapy secreted for six to 19 days if the animal survived initially. The longest period of function in a graft was seen in a dog which survived two and one-half months.

The incretory* function in isotopic pancreas grafts was determined by glucose tolerance tests; the excretory function was tested enzymatically in the fistula secretions (Figures 2 and 3). A comprehensive report of our methods of pancreatic homografting will be reported elsewhere.

Summary

A method of pancreas perfusion is described, using amino acid stock solution and an enzyme-inhibitor as perfusate, which replenishes proteins metabolized by the pancreas and neutralizes liberated enzymes.

We failed to see any acute pancreatitis or its sequelae with this method of perfusion in 16 transplant operations.

Prejudices

There is nothing to be said against the retention of prejudices. I believe in every man having a good stock of them, for otherwise we should be flimsy, ineffective creatures, and deadly dull at that.—John Buchan

Biogenic Stimulant

Athletes were objects of unusual and highly instructive experiments (at the Odessa Institute). And it turned out that there was a close connection between a foot race and biogenic stimulants. Filatov and his associates found this connection.

The eyesight of the runners was examined just before the starting gun. The race began, and after the runners crossed the finishing line their eyesight was examined again. It had become sharper. The scientists wanted to know why. The runners had not had any transplantations. They had not had injections. No biogenic stimulants had been introduced into their systems.

A simple experiment helped the scientists to get to the bottom of the riddle. After the race a few drops of blood were taken from one of the runners, and dissolved in water. The solution was injected into another person who had not run in the race, and had been sitting quietly in his laboratory. His eyesight improved.

Clearly, this happened because the blood taken from the runner contained substances that improved the eyesight. They must have appeared in the blood during the race—a product of intense muscular effort.

More blood was taken from the runners to determine the nature of these substances. Liquid extracts of this blood were tried in test subjects. The check-up revealed that their properties and effects coincided with those of biogenic stimulants.

This led to a new conclusion: Work increases the output of biogenic stimulants. Work, therefore, is a physiological necessity, and is beneficial to the system. Filatov says that "by working not only mentally, but physically as well, a man tones himself up and raises his psychophysical level."*

The Tongue-Scraper

I think more of this little implement (the tongue-scraper) on account of its agency in saving the Colony at Plymouth in the year 1623. Edward Winslow heard that Massasoit was sick and like to die. He found him with a household of people about him, women rubbing his arms and legs, and "friends making such a hellish noise" as they probably thought would scare away the devil of sickness. Winslow gave him some conserve, washed his mouth, *scraped his tongue,* which was in a horrid state, got down some drink, made him some broth, dosed him with an infusion of strawberry leaves and sassafras root, and had the satisfaction of seeing him rapidly recover. Massasoit, full of gratitude, revealed the plot which had been formed to destroy the colonists, whereupon the Governor ordered Captain Miles Standish to see to them; who thereupon, as everybody remembers, stabbed Pecksuot with his own knife, broke up the plot, saved the colony, and thus rendered Massachusetts and the Massachusetts Medical Society a possibility, as they now are a fact before us. So much for this parenthesis of the tongue-scraper, which helped to save the young colony from a much more serious scrape, and may save the Union yet, if a Presidential candidate should happen to be taken sick as Massasoit was, and his tongue wanted cleaning,—which process would not hurt a good many politicians, with or without a typhoid fever.*

The Pulmonary Vascular System

Problems in Anatomy and Hemodynamics

R. FELIX, M.D.*
P. GEISLER, M.D.*
A. DUX, M.D.*
E. BUCHELER, M.D.*
Bonn, West Germany

OF ALL ORGANS the lung is the only one whose vascular system accommodates the entire cardiac output. Therefore a method of determining the functional cross-section of the pulmonary vasculature is of particular interest.

Problems

The direct determination of the anatomy of the pulmonary vascular system is possible only by angiographic methods. By means of the so-called selective and terminal angiograms[1-5,10,17,18] we are enabled to assess the function of terminal pulmonary vessels and to observe rarefactions and constrictions, especially in the precapillary and capillary vasculature.

The Flow Velocity

The pattern of distribution and flow velocity enables us to derive the cross-sectional distribution within the precapillary and capillary beds. Normally the flow velocity diminishes geometrically with an increase of the cross-section. Bolt, Rink and Semisch found that a reduction of the capillary cross-section results in a lowering of the flow velocity in the small arteries and arterioles, while the contrast medium traverses the capillary field with increased velocity. This important observation leads to the assumption that in the presence of tissue loss, as in pulmonary emphysema, there is a changing cross-sectional distribution between capillary, precapillary and arterial space. Thus the tissue loss affects the capillary system more than any other. The loss of alveolar walls first affects the capillary field[18]; the precapillaries and arterioles are involved only at a later stage. The redistribution of hemodynamic and geometric cross-sections, however, is not affected by these changes.

Vascular Capacity

While selective and terminal pulmonary an-

*From The Institute for Radiology and Radio-Therapy, Director: Professor Dr. P. Thurn, and from The Department of Surgery, Director: Professor Dr. A. Gütgemann, University of Bonn.

giography permits an estimation of the hemodynamic cross-section, it is still impossible to assess the elasticity and reactivity of the pulmonary vessels. A change of the cross-sectional area within the vascular system can neither be provoked nor be measured locally. A determination of the extent of vascular cross-sectional regulation makes it possible to relate a given cross-sectional measurement to the possible limits of vascular reactivity. Variations in pulmonary vascular capacity have been repeatedly found,[18,11] and they explain changing circulation times in the same pulmonary system with identical pulmonary artery pressures.

Observations

Vasoconstriction in the Lung

The first goal in evaluating the pulmonary vascular system should be an approximate determination of the pulmonary vascular cross-sectional area and of its maximal and minimal values. Reversible change of the cross-sectional area in the pulmonary vasculature and its

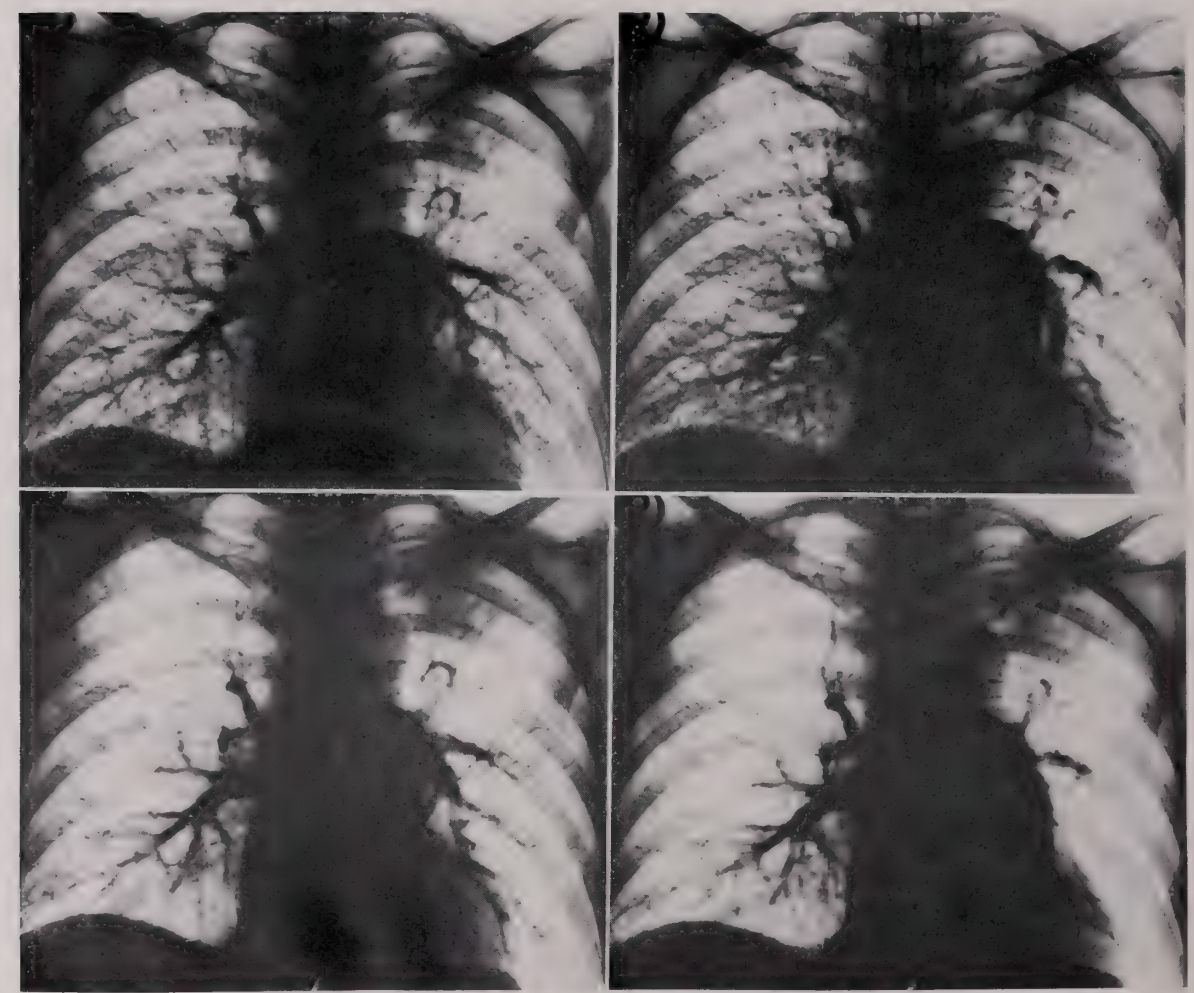

Fig. 1—Fifty-year-old female with bronchial carcinoma in the apical segment of the left upper lobe.

(a and c) Pulmonary arteriogram during normal ventilation under Fluothane anesthesia.

(b and d) Pulmonary arteriogram during suspension of ventilatory diffusion of the left side during Fluothane anesthesia; 66% of the heart minute volume passes the right and 34% passes the left lung.

(a) Uniform vascular density and vascular diameters in both lungs, showing no difference in radiolucency and flow velocity.

(b) Identical phase of dye passage as in Figure 1a. Distinct functional rarefaction of the vessels and diminution of vascular diameters on the left side. "Functionally hyperlucent lung" left.

(c) Early arterial phase (2 seconds before Figure 1a). Bilaterally equal inflow velocity of blood contrast medium mixture.

(d) Identical phase of contrast medium passage as in Figure 1c. Distinct diminution of inflow velocity on the left side as compared with the right.

determination has been shown and described by us in previous publication.[8,9] Figures 1a and 1b depict such localized cross-sectional change. In Figure 1a the vascular cross-sections of both lungs are practically identical, whereas Figure 1b shows a distinct rarefaction of vascular density and decreased arterial width in the left lung indicating an effective vasoconstriction in that lung.[6] This phenomenon was discovered by Euler and Liljestrand and has been named "alveolo-vascular reflex" by Rossier and coworkers. It connotes an inter-relationship between alveolar gas pressures and hemodynamic resistance. We have defined the result of this reflex as the "functionally, unilaterally hyperlucent lung."[9]

Recognition of this phenomenon by angiographic means resulted in the discovery of a second phenomenon: the redistribution of linear flow velocity between both lungs. Figure 1c demonstrates a bilaterally equal inflow-velocity of the blood-contrast-medium mixture, while Figure 1d shows a distinctly diminished inflow velocity into the left lung during a provoked cross-sectional reduction. According to the law of Hagen-Poiseuille the flow through a tube varies with the fourth power of the radius. The velocity of flow is defined as the quotient of flow over the time unit over the cross-section. Thus in the presence of parallel vessels a reduced cross-section results in a reduced flow velocity.

A comparison of Figures 1d and 1c definitely proves the validity of this theory: 66% of the cardiac minute volume passes through the right lung and 34% through the left lung during the phase depicted in Figure 1d.

Changing Alveolar Gas Tension

Selective angiography should be able to demonstrate vascular changes in response to changing alveolar gas tensions as long as these reactions occur homogeneously in all segments. However, such homogeneous reactions are quite rare. Emphysematous changes in the elderly usually occur in uneven distribution patterns, resulting in a mixed picture of more or less emphysematous deformation. Since the changes of the vascular cross-sectional areas parallel the development of emphysema in the different regions of the lung, the findings of a limited cross-sectional vascular area are not necessarily representative of the entire lung.

Figure 2 is a typical example of a vascular

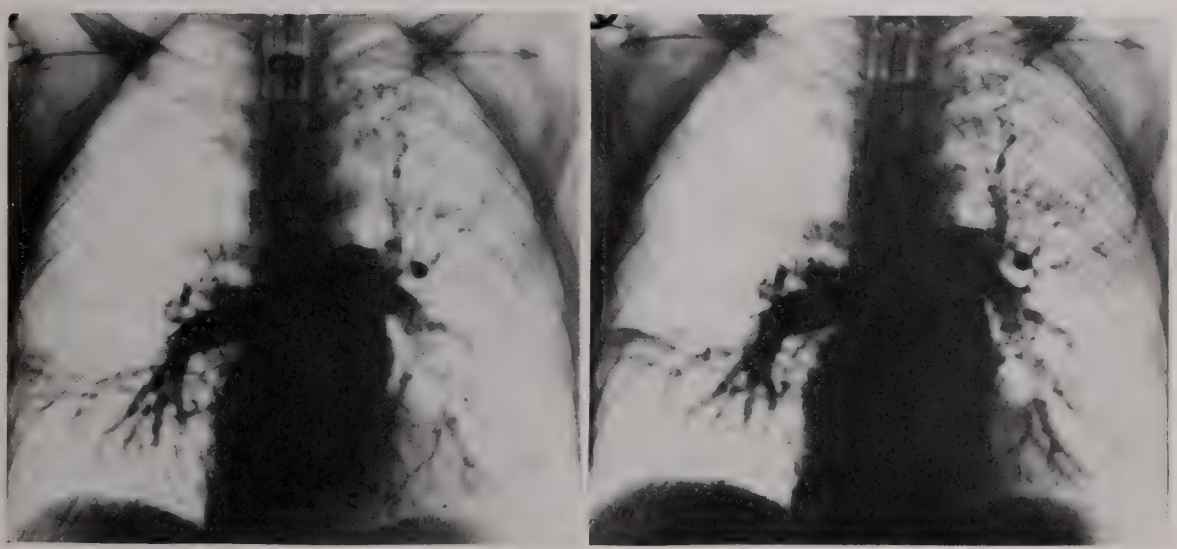

Fig. 2—Fifty-year-old male with bronchial carcinoma in the anterior segment of the right upper lobe. Primary vascular rarefaction in the enlarged right upper lobe, due to emphysema and tumor. Emphysema also present in the left lower lobe.

(a) Pulmonary arteriogram during normal respiration under Fluothane anesthesia. Approximately even vascularization in the right lower and the left upper lobe.

(b) Pulmonary arteriogram during right-sided suspension of respiratory gas diffusion under Fluothane anesthesia; 82% of the cardiac minute volume passes the left and 18% passes the right lung.

Functional vascular rarefaction in the right lower lobe. Increase of vascular density in the left upper lobe. Unchanged findings in the left lower and right upper lobe.

reaction to a change of alveolar gas pressure; Figure 2a shows the primary vascular cross-sectional reaction in this lung. The vessels in the enlarged right upper lobe are rarefied due to tumor and emphysema. Advanced emphysema is also seen in the left lower lobe.[13] If the vascular system of the right lung is exposed to equilibration of the alveolar gas pressures to the mixed venous level, then a reduction of the cross-sectional area in the right lower lobe can be noted (Figure 2b). This corresponds principally to the reduction in the left lobe shown in Figure 1b, although to a smaller degree. A further narrowing of the vasculature in the right upper lobe is obviously impossible. While in Figure 2a the vascular density is about equal in the right lower and left upper lobes, it is distinctly different in Figure 2b. Here the reduction and cross-sectional area at the right lower lobe has been largely compensated by the left upper lobe. Areas with more marked emphysematous changes in the left lower lobe are incapable of these compensatory reactions.

Figure 2b shows the entire lung of this patient is composed of four different vascular areas which react differently. This multiplicity of behavior cannot be captured by selective angiography, which is incapable of registering the constrictive capacity of the pulmonary vasculature as well as of providing a general picture of the pulmonary vasculature. During the circulatory phase shown in Figure 2b, 82% of the heart minute volume passes through the left lung and 18% through the right lung.

Figure 2 illustrates another pathophysiological problem. The changes in the left lower lobe seen in Figure 2a may be an expression of alveolar hypoventilation with the resulting changes in alveolar gas tensions. If in these cases the observed vascular constriction is of a functional nature,[7,12] it will disappear when a vascular constriction is induced in the contralateral lung. By reacting in this fashion the normally ventilated lung demonstrates an adequate cross-sectional vascular reserve which enables it to accommodate the increased flow and the increasing vascular distention factor. Organic and functional vascular constrictions in the normally ventilated lung can thus be distinguished.

In the case shown in Figure 2 the cross-sectional areas are morphologically "fixed." Morphology alone does not suffice for a certain differentiation between functional and organic constriction. However, the capacity of the pulmonary vascular system to alter the cross-sectional diameter is of great importance in the preoperative assessment when a pneumonectomy is planned.

Influence of Age

Angiographic evidence indicates that the capacity of cross-sectional vascular regulation diminishes with increasing age; however, this does not exclude the possibility of persistent reactivity of the arteriolar and precapillary vasculature. This can be shown by indirect means. A 69-year-old male patient with a bronchial carcinoma of the left upper lobe serves as an example. Figure 3 shows definite rarefaction of the vasculature of the left side and emphysema in the right upper lobe. When the alveolar gas diffusion is interrupted, as shown in Figure 3b, there is only a very moderate rarefaction of the vasculature. The interdependence of the hemodynamic cross-section and flow velocity again becomes evident in both lungs toward the end of the passage of the contrast media. Figure 3c shows a uniform distribution of dye in the central veins in the presence of unchanged pulmonary hemodynamics. If, however, the gas diffusion is abolished (Figure 3d) the passage of contrast media in the normally ventilated right lung is already completed while there is still filling of the central veins of the left side similar to Figure 3c. A decreased diameter of the dye-filled veins on the left side is also noticeable, in comparison to Figure 3c.

Our experience with 75 patients indicates that this marked difference in flow velocity cannot be caused by the relatively small change in cross-sectional area in those vessels which are demonstrable by angiographic means. Cross-sectional changes in the arteriolar precapillary segments which occupy a much larger cross-sectional area have greater influence on the resistance and thus on flow volume and flow velocity. Therefore, we assume that there is a sufficient reactivity of the arteriolar segments persisting in this patient.

The third example also shows that a reduction in vascular cross-sectional surface, be it of

organic or functional origin, does not exclude further vascular reactivity.

Clinical Application

Risk of Operation

In deciding on a pneumonectomy the question arises whether or not the remaining lung can accommodate the entire cardiac output while maintaining a normal pressure head.[1-5,17,18] Advanced emphysema is usually accompanied by functional and morphological diminution of the pulmonary vascular bed,[12,16] and the operative risk in pneumonectomies is thereby increased. Complete excision of a lung tumor would be ill-advised if it should lead to irreversible right heart failure.[17,18]

Postoperative Prognosis

The commonly used pulmonary function studies, such as spirography and blood gas analyses, demonstrate only the patient's preoperative condition. An attempt to gain some information for the postoperative prognosis is warranted. Selective pulmonary angiography[1-5,17,18] can demonstrate the vascular bed in selected areas at a given time and show the degree of emphysema. This method, however, is not suited for assessing the vascular cross-

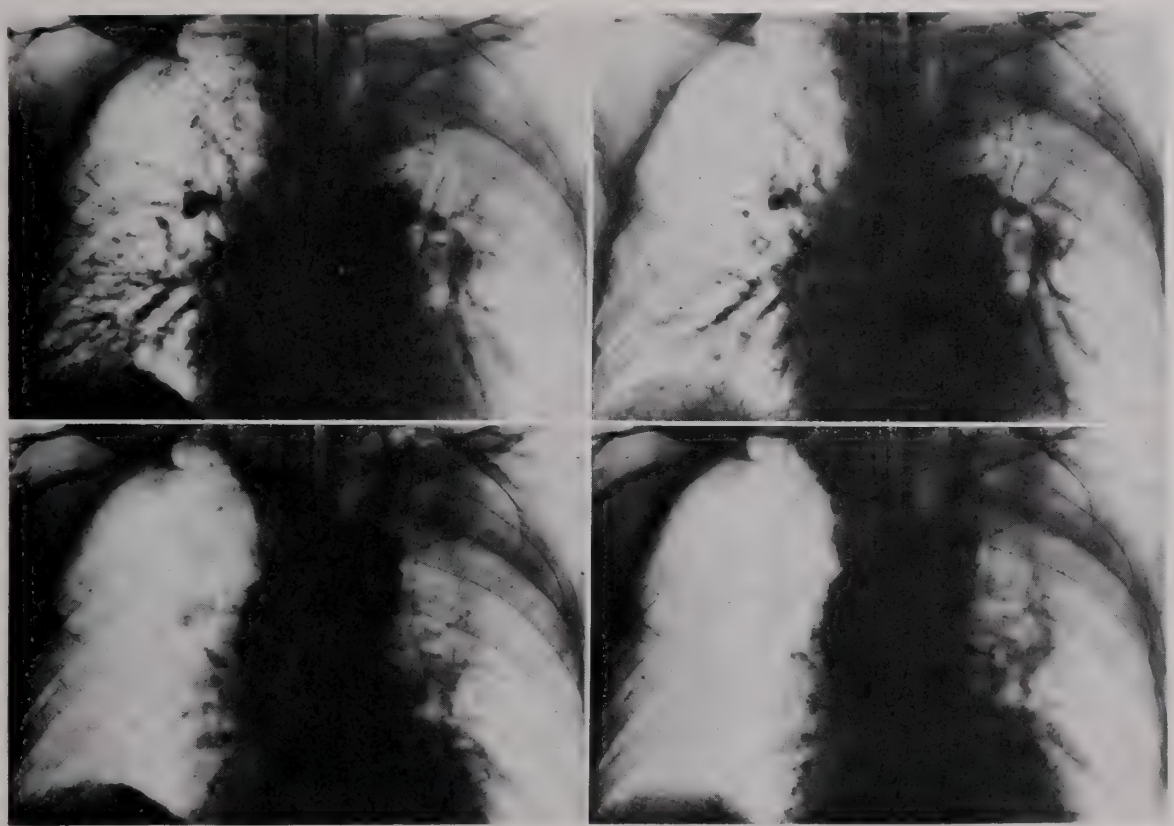

Fig. 3—Sixty-nine-year-old male with bronchial carcinoma in left upper lobe. Primary vascular rarefaction in left lung. Tumor compression of left-sided arteries of the apical and posterior upper lobe segments and of the main branch to the lower lobe artery.

(a and c) Pulmonary arteriogram during normal ventilation under Fluothane anesthesia.

(b and d) Pulmonary arteriogram during left-sided suspension of ventilatory gas diffusion under Fluothane anesthesia; 80% of the cardiac minute volume passes the right and 20% passes the left lung.

(a) Late arterial and early venous phase. Emphysema in right upper lobe.

(b) Identical phase of contrast media passage as in Figure 3a. Small increase of vascular rarefaction in the left lung. Only small increase of vascular density on the right side. Slightly increased inspiratory position as compared with Figure 3a.

(c) Late venous phase (2.6 seconds after Figure 3a). The large central veins are equally contrasted on both sides.

(d) Identical phase of contrast medium passage as in Figure 3c. On the right side the contrast medium passage is completed while there is still filling of the more central veins on the left side. The venous diameters on the left side are slightly diminished as compared with Figure 3c.

sectional surface and the vascular capacity. This capacity is the decisive factor for the postoperative fate of the right heart.

The Method of Pulmonary Angiography

Our method[8] consists of pulmonary angiography during unilateral suspension of alveolar gas diffusion. It shows the propensity of the pulmonary arteries and veins to change their diameter in response to the suspension of gas diffusion. A shift of a portion of the cardiac output from the non-ventilated to the normally ventilated lung would be impossible if the vascular diameter on both sides were fixed. The ability of the pulmonary vascular bed to dilate or to constrict can be seen simultaneously in both lungs.

The vascular diameter in the pulmonary bed diminishes with progressive tissue loss and all vascular reserve may perish. A functional reduction of the vascular pulmonary bed becomes impossible and pulmonary perfusion with the normal cardiac output then brings about increased pulmonary artery pressures in order to maintain flow. The increased intravascular pressure results in increased wall tension. The angiographic demonstration of marked functional decrease of the vascular cross-sectional area indicates the absence of marked pressure increases in the pulmonary vascular bed, which means that there is a compensatory capacity of the vascular cross-sectional area. The exact pulmonary artery pressures at which cross-sectional regulation ceases is still to be determined. This pressure depends also on the elasticity of the vessel wall.

The determination of oxygen consumption and blood gas analyses during suspension of ventilatory diffusion in one lung, while the other lung is normally ventilated, enables us to judge the efficiency of the ventilated lung and to calculate the shift of the cardiac output.[8]

Summary

Selective pulmonary angiography during normal ventilation does not permit a complete assessment of the morphology and function of the pulmonary vasculature. The structure and function of the pulmonary vessels vary greatly throughout the lung, especially in older people with emphysema and bronchial carcinoma. The demonstration of all lung vessels and a simultaneous assessment of the capacity of pulmonary vessels to change their diameter in all portions of the lung permit us to judge the adaptability of the pulmonary vascular bed to marked flow changes and thus the fate of the right heart after pulmonary resection.

The extent of pulmonary vascular adaptability can be seen after unilateral suspension of respiratory gas diffusion without simultaneous mechanical impairment of the lungs, and this regulatory capacity permits predictions for the functional vascular diameters. It is possible to distinguish functional pulmonary vascular constrictions due to localized alveolar hypoventilation from anatomically fixed circumscribed vascular narrowing. The action and interdependence of physiological and pathophysiological parameters are discussed.

Cardiac Arrest in Children

M. DOHMEN, M.D.*
Bonn, West Germany

CARDIAC ARREST carries a much more ominous connotation in children and infants than in adults. While hereditary and circulatory diseases are the main factors in middle and older age,[2,4,10,16,24] children with normal hearts are more frequently victims of acute cardiac arrest than are children with heart disease.[14]

Twenty percent of the 1710 cases collected by Stephenson were children under the age of 10 years. Successful resuscitation was possible in 30% of all ages.[21,31] Children have a more favorable prognosis than adults.[31] It is a fact that acute cardiac arrest occurs more frequently during heart surgery than with other operations, and that resuscitation succeeds more frequently.[7] Therefore we have to concede a special place to cardiac surgery in any discussion of cardiac arrest and resuscitation.

Cardiac Arrest

Incidence

There were 18 children under 14 years in a group of 96 patients who suffered acute cardiac arrest while in our surgical clinic (Figure). Seven of them came to us with conditions that were directly responsible for the cardiac arrest: thoracic injuries, congenital atresia of the esophagus, aspiration of foreign bodies, other aspirations, tetanus.

Eleven children were admitted with benign conditions and only one child had to come to surgery because of appendicitis. Thus it appears that cardiac arrest was predominantly caused by exogenous factors. Our figures confirm that lack of oxygen was the primary reason.

Causes

One is easily deceived when dealing with cardiac arrest. Frequently one incriminates toxic or allergic factors (roentgen-contrast media, drugs, narcotics and digitalis prepara-

*From the Surgical Department, University of Bonn. Director: Professor A. Gütgemann, M.D.

tions), mechanical injury to the heart, cooling, changes in electrolytes, acid-base balance, bacterial toxins and neurogenic reflexes. We must recognize, however, that these factors rarely lead to cardiac arrest per se, but primarily to a respiratory deficit or blood loss (Table). Frequently these two forms of hypoxia are combined with other pathophysiologic mechanisms, which can not always be defined.

Case Report

A 21-month-old boy with perforated duodenum and peritonitis was prepared for surgery, when ventricular fibrillation occurred. The general condition of the child with peritonitis and a high degree of dehydration was grave. During pulmonary aspiration the respiration was handicapped by the distended abdomen.

Previously, while being transported to the hospital,

the child had received artificial respiration by mask, and resuscitation of the heart was accomplished by external cardiac massage. A subsequent pneumothorax necessitated a Buelau-drainage and, since the bronchial tree could not be cleaned sufficiently, a tracheotomy was performed. Finally respiration and circulation stabilized enough to permit abdominal surgery. After the operation another episode of ventricular fibrillation occurred but was successfully managed by external cardiac massage, defibrillation, and intracardiac injection of suprarenin-calcium; but when functional cardiac arrest recurred for the fourth time, all attempts at resuscitation failed.

Resuscitation

The advantages and disadvantages of the external cardiac massage is still the subject of many clinical and experimental studies.[6,9-12,19-21,23,25,28,32,33,36,38,39] The majority of authors favor external cardiac massage in infants or children. Even though all details of procedure have been worked out,[39] we think it advisable to indicate some directives which have been rarely mentioned.

All methods of external cardiac massage are physically exhausting, whether one uses the two-hand, one-hand, one-hand-thumb or two-finger method. The two-hand method is recommended for children of school age. The child should be placed supine on a rigid foundation. Placing a board on top of a mattress is insufficient as it will not prevent the yielding of the mattress. The rhythmic compressions of the sternum, which are meant to prevent a lateral escape of the heart, are thus less effective; likewise the compression is ineffective in spite of great expenditure of power. The patient should lie on the ground or on the floor. This is true also for the one-hand and the two-finger methods, which are more appropriate between the first and fifth year of life. In newborns and infants up to the age of six months we prefer the compression of the sternum between the two thumbs and the palms of the hands. The movements are symmetrical and applied vertically to the frontal plane of the body. The effort is thus distributed evenly to both hands and constant changing can be avoided. The resuscitation procedure should include: electrocardiography for differential diagnosis, electrical defibrillation, intracardiac injection of Alupent according to type of cardiac arrest, suprarenincalcium, adrenalin, potassium; also control and correction of metabolic acidosis, fluid replacement, and intravenous sodium bicarbonate.

Comments

Forced Breathing and Intubation

We saw in this child a sequence of complications, in which respiratory problems were prominent. It is well known that forced oxygen breathing can lead to distention and even rupture of the normal stomach.[27,37] Artificial respiration by mask is even more likely to emphasize and aggravate the pneumoperitoneum, which occurred in this instance from perforation of the duodenum. For this reason one ought to prepare for intubation as soon as ulcer perforation is suspected.

Tracheotomy

One should hesitate to employ tracheotomy because of the inherent complications in children.[1,5,18] A pneumothorax need not have dire consequences if it is recognized in time and corrected; but the mucopurulent tracheobronchitis, which often follows, should be taken seriously because it may complicate the maintenance of open respiratory passages. The intubation tube may be plugged at times by mucus, and atelectasis may occur within a short time. Even careful and intensive nursing with regular aspiration of the bronchial tree with soft curved catheters and utilization of the most modern aspiration or respiratory apparatus may not protect from the danger of atelectasis.

The cardiac arrest proper occurs during the introduction of the catheter, during the changing of tubes or during change of the child's position. Thus the importance of the so-called reflex cardiac arrest comes to mind.

Case Report

A nine-year-old boy with tetanus received mechanical respiration through a tracheotomy. During tracheobronchial aspiration through the tracheostomy asphyxia and cardiac arrest occurred.

Similar events, such as the introduction of a bronchoscope to recover an aspirated foreign body in a three-year-old boy, led to cardiac arrest.

These events remind us of an experiment by Sloan, to which Schwaiger[29,30] attributes fundamental importance: stimulation of the vagus in a dog led to cardiac arrest only when it fol-

lowed hypoxia. We believe with Tschirren, Nissen et al. that reflex cardiac arrest without other complications is rare during surgery.[17,26]

Hypovolemia

In six children cardiac arrest was preceded by hypovolemia (Table). While blood loss is easily overestimated in the adult[3] the opposite is true for children. It is not so much the obvious arterial hemorrhage which leads to hypovolemia, since it is easily recognized and remedied. The greater danger threatens children who bleed slowly, drop by drop, during procedures in which a substantial blood loss is not expected. All signs of imminent hypovolemia are difficult to measure in children.

Conclusions

Seven of the 18 children left the clinic after acute cardiac arrest in apparent good health and without central nervous system defects. In five of these children the cause of arrest had not been established. A citation of possible causes would serve neither prophylaxis nor therapy. We can only state that inadequacies have become apparent within our surgical domain (asphyxia, hypovolemia), which offer a basis for prophylactic measures against cardiac arrest.

Synthesis of Greek and Christian

Looking back we can say that the Greek concept of health was primarily physical and that Greek hygiene was aristocratic. The Christian concept of health, on the other hand, was primarily spiritual and Christian hygiene was catholic, addressing itself to all. The synthesis of both, the development of a concept which would embrace physical and mental health without compromise, the revival, general adoption, and democritization of the *mens sana in corpore sano* of Juvenal—this ideal becomes the program of the ensuing centuries.*

The Dissociated Brain Death

Clinical and Electroencephalographic Criteria for Determination of Death

H. PENIN, M.D.*
C. KAUFER, M.D.*
Bonn, West Germany

A COMPLETE FUNCTIONAL deficiency of the brain extending over several hours, the sequel to a transitory anoxemic injury after a traumatic brain damage or from severe metabolic anoxia is, according to past experiences, irreversible. Even if in this condition the circulatory system is stimulated by intensive reanimation for many hours or even days the eventual death of the individual is inevitable. Thus over a certain time period a dead brain, accompanied by a pulsating heart, can be spoken of as a dissociated brain death.

These experiences raise doubt with regard to the present concept of the clinical determination of the time of death, which, when oriented on the parameter of the heart function, is based on indirect signs of heart and circulation stoppage. Perhaps it is as correct to identify the death of the individual with the brain death as with the death of the heart[3,19,22,23] because of the reciprocity of brain function with physiological integrity. Consequently, an individual with a dissociated dead brain, in spite of a pulsating heart, must be declared dead.

In this article the scientific-biological problem, rather than the forensic, legal, moral and religious aspects, is presented.

Paramount and pertinent are three questions that must be considered together before death is declared when there is still a beating heart and one chooses to discontinue re-animation. (1) Is the dissociated brain death absolute, that is, unmistakable? (2) Can the determined nonfunction of the brain be reconstituted? (3) After what time is dissociated brain death absolutely irreversible?

Diagnosis of the Dissociated Brain Death

Clinical Definition

The clinical definition of cerebral death according to Schwab[22] includes: (1) deep coma with atony and absolute areflexia; (2) nonresponse to strong sensoric stimulation; (3)

*From the Neurologic Clinic (Director: Prof. Dr. H. J. Weitbrecht) and Surgery Clinic (Director: Prof. Dr. A. Gütgemann) Rheinische Friedrich-Wilhelm-University of Bonn, West Germany.

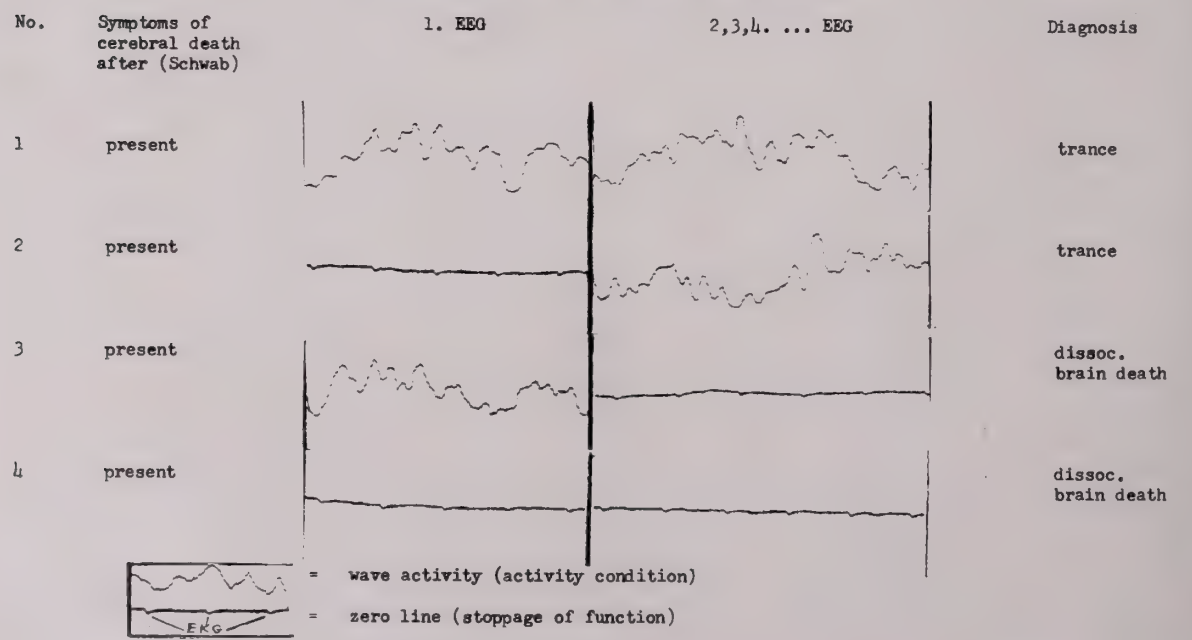
mydriasis with absolute pupil fixation; and (4) absence of spontaneous breathing.

A single registration of these symptoms is not sufficient, but a continuous observation over a certain period of time is necessary.

For the objective evaluation of the clinical and neurological findings various other examinations are available;[16,4,9,20] but these may not be wholly satisfactory.[5,25] Recent experiences have proven the electroencephalogram to be the most reliable instrument because it is the only objective method whereby brain function can be absolutely measured. The brain potentials and the modulation through subcortical influences are strongly reflected. In the case of death there is absolute cessation of the electrical potential and isometric curve pattern.

The isometry in the electroencephalogram, however, allows two interpretations: first, the sign of an irreversible loss of function (brain death), and secondly, the expression of a reversible functional block of the brain. Thus one does not conclusively know from the isometric curves which cerebral dysfunction is the cause of the cessation of electrical potential, although a differentiation is possible if one applies the old principle as defined in the preceding clinical picture. Thus the question of the time of brain death can be accurately determined when clinical symptoms of cerebral death are present.

Electroencephalographic Identification



When these assumptions are fulfilled one can begin to evaluate the electroencephalograms under strict technical observations:

1. Maximum at least three times the intensity (21 mm = 50 uV) which must be used in accordance with the standard of the electroencephalograph.
2. Simultaneous registration of the electrocardiogram and breathing as an additional proof of the technical efficiency of the electroencephalogram apparatus and identification of superimposed artifacts.
3. Continuous electroencephalogram diversion (lead-off) of a minimum of 20 minutes with no less than eight intensification channels in order that intermediate bioelectrical deviations (variations) are not overlooked.

Besides being inadequate the electroencephalogram so obtained may even give rise to serious error. Only the pattern of several synchronized neurologic-brain electrical findings

TABLE I

Continued Clinical-Electroencephalographic Correlation in Dissociated Brain Death with Present Heart Activity

permits a final and definitive opinion on brain death. The latter corresponds to the clinical and electroencephalogical absolute stationary appearance, because death contrary to disease has no comprehensible progress profile.

Death or Resuscitation

A functional resuscitation was observed in short-term intervals[11] after studying the brain wave in conjunction with surgery and after a successfully re-animated cardiac arrest, especially in hypothermia. Furthermore, reversible results have been noted in cases of deep anesthesia[15,24] and in poisoning with hypnotics.[11]

Isoelectrical Electroencephalogram

Table 1 shows the progressive profile of clinical-electroencephalogical findings in the four instances. It was assumed that death (Schwab) was evident at the time of the first electroencephalogram-lead as well as in the third and fourth leads during the further observations. The zero-lines do not show rhythmic down-directed variations corresponding to the action potential of the electroencephalogram.

It is clearly shown that the electroencephalogram as an indicator for the determination of brain death is of value, but only the subsequent readings determine the final diagnosis of "brain

TABLE 2

death" as differentiated from "trance" (Scheintod). The question then arises immediately: after what time interval does a restoration of neurological and brain electrical impulses fail to appear?

Determination of Time of Death

The relatively small number of cases observed with the isoelectrical electroencephalogram and the clinical correlation of the findings do not allow a clear-cut answer as to the moment of death. We concur with other authors (Scharfetter and Schmoigal) that there is no agreement on how long an electroencephalogram must remain isoelectric before a dissociated brain death can be confirmed. Schwab proposes to wait through two 30-minute time periods; Fischgold[23] three hours, Spann, Kugler and Liebhart six hours, Jouvet more than 24 hours, and our French colleagues (Ordre National des Medicins) 48 hours; whereas Müller, Scharfetter and Schmoigl as well as Rittmeyer and Bushart leave the question open.

It would appear that a responsible decision could be made when an isoelectric electroencephalogram in conjunction with the clinical brain death exceeds four hours, because reports of isoelectric curves with successful resuscitation beyond the four-hour limit[1,3,13,18,24] fail to withstand critical analysis: either precise clinical data were not given or the electroencephalogram was not completely isometric. We doubt that a large series would prove any exception showing that after the expiration of four hours a functional recovery of brain activity occurs. Thus we believe that basically the determination of the time of death with the aid of the isometric brain current pattern must be established on a large series of cases and on uniform observation criteria, rather than on the opinion of an individual who may have made a few observations.

A corticogram or subcortical lead with the aid of deep electrodes[6,12] to confirm brain death will remain irrelevant until it has been proven that the electroencephalogram from the scalp does not resolve the problem.

Our Observations

During a study of disturbances of consciousness during surgery we noted 12 instances in which dissociated brain death was obvious as observed by continuous brain electric isometry. A total of 28 electroencephalograms were made. During the observation time the heart performance was satisfactory and the circulatory system was supported with vasoconstrictive medication. In each case continuous breathing was supported. Complicating causal factors for a disturbance of the consciousness in form of a metabolic disorder[2,7] were excluded. The clinical criteria of brain death remained unaltered, and electroencephalographic tracings demonstrated that brain activity failed to occur after isometry was established. All patients expired in spite of our efforts (Table 2).

Discussion and Summary

Successful re-animation in the past few years now requires a revision of the criteria pertaining to the time of death, which up to this time depended upon the activity of the heart and circulatory system. The brain function is now assigned a more dominating role in the decision between life and death. Furthermore, recent homologic transplantations, particularly of the heart, force us to conclude that cessation of brain function is a more logical determination of death even though the heart is pulsating.

For the diagnostic assurance of the dissociated brain death the electroencephalography as a quantitative procedure has become vitally important: the isometry in the electroencephalogram confirms the clinical diagnosis of cerebral death; but a proven wave activity negates brain death. However, this is not sufficient. We must ascertain beyond all statistical doubt with the aid of the bioelectric curve pattern the effective time interval associated with irreversible death of the brain.

Thus there should be available in the future fundamental investigations covering a large series in order to establish a definitive time limit before death can be pronounced. The single investigator cannot do this on the limited basis of his own few patients. Thus we have arranged a cooperative association with surgeons, neurosurgeons, neuropsychiatrists, and electroencephalogram-versed-neurologists to clarify conclusively the "effective time of death." We speak of "effective death time" because in a single case the precise moment of

death cannot be exactly determined. When the clinical diagnosis of brain death can be proven objectively by electroencephalography, then a declaration of death in spite of a pulsating heart will raise no objection medically.

Legal obligations and responsibility for setting the time of brain death, when the heart is still pulsating, further complicate the problem, considering the aspects of donor selection for a homologic organ transplantation. Because of an optimal short ischemic time a dead brain with intact circulation, in contrast to a cadaver brain, allows systematic transplantation and a more favorable prognosis for the recipient.

Because of the effective use of resuscitation methods and the increasing number of re-animation cases the danger arises that in hopelessly brain-damaged patients unnecessary revival efforts will be made that will not, however, improve the patient's prognosis. It must not be the goal of modern medicine to maintain decerebrated heart-lung individuals, because medical care without a chance of patient improvement is for both relatives and nursing personnel depressing and futile.

An Itinerant Vaccinator

Smallpox was a scourge that regularly swept down on the settlements of the Atlantic seaboard. To his dying day, Washington carried its marks on his face, and because it was so feared, early American physicians made every effort to stem or prevent its inception. . . . In 1798 Dr. Waterhouse of Cambridge came out thoroughly for vaccination. He soon had followers, not the least of whom was a Sylvanus Fancher of Waterbury, Connecticut. Called Dr. Fancher by courtesy, this odd stick wandered about from town to town and his fame spread all over New England. His appearance must have made him a fearsome person. He wore "velvet small clothes, a parti-coloured waistcoat from which dangled a half a dozen watch-chains and trinkets for the amusement of the little folks, and a faded blue coat—all these surmounted by a slouched hat overhanging green goggles." Despite his appearance, he seems to have known his business, for he invented and used a vaccinating instrument, a silver bar that carried a concealed lancet with which the incision was made.*

How people love an old saying! They are always quoting "There is nothing new under the sun," yet there is something new every day.—E. W. Howe

Mark Waters was a chain smoker. Wonder who'll get his office?

Too bad about Mark. Kept hearing the same thing everyone does about lung cancer. But, like so many people, he kept right on smoking cigarettes. Must have thought, "been smoking all my life... what good'll it do to stop now?" Fact is, once you've stopped smoking, no matter how long you've smoked, the body begins to reverse the damage done by cigarettes, provided cancer or emphysema have not developed. Next time you reach for a cigarette, think of Mark. Then think of your office —and your home.

Let's be specific about Campbell's Soups... and *reducing diets*

There are more than 30 million people in America who are overweight. During the next year, you probably will see more than 1,000 of them in your own practice.

One good way to help these patients is to give them a reducing diet based on ordinary eating patterns.

Campbell has prepared a sensible plan for weight control based on ordinary eating patterns. The plan consists of a patient instruction booklet and a set of menus which provide approximately 1,200 calories daily. The menus are balanced to provide the minimum daily requirements of nutrients.

To obtain a supply for your office write to:
Campbell Soup Company, Box 265, Camden, N. J. 08101

In childhood

Warnings: Lomotil should be used with caution in patients taking barbiturates and with caution, if not contraindicated, in patients with cirrhosis, advanced liver disease or impaired liver function.

Precautions: Lomotil is a Federally exempt narcotic with theoretically possible addictive potential at high dosage; this is not ordinarily a clinical problem. Use Lomotil with considerable caution in patients receiving addicting drugs. Recommended dosages should not be exceeded, and medication should be kept out of reach of children. Should accidental overdosage occur, signs may include severe respiratory depression, flushing, lethargy or coma, hypotonic reflexes, nystagmus, pinpoint pupils, tachycardia; continuous observation is necessary.

Adverse Reactions: Side effects reported with Lomotil therapy include nausea, sedation, dizziness, vomiting, pruritus, restlessness, abdominal discomfort, headache, angioneurotic edema, giant urticaria, lethargy, anorexia, numbness of the extremities, atropine effects, swelling of the gums, euphoria, depression and malaise. Respiratory depression and coma may occur with overdosage.

Dosage: The recommended initial daily dosages, given in divided doses until diarrhea is controlled, are as follows:

diarrheas...

- careful supervision
- electrolyte replacement
- specific anti-infective therapy

and...

LOMOTIL®

TABLETS/LIQUID

Each tablet and each 5 cc. of liquid contains:
diphenoxylate hydrochloride ..... 2.5 mg.
(Warning: May be habit forming)
atropine sulfate .....0.025 mg.

LOMOTIL, in conjunction with specifically indicated medical management, may be lifesaving in children with severe diarrhea.

Lomotil lowers the excessive intestinal propulsion characteristic of diarrhea. This reduction of precipitate intestinal flow allows a normal or more nearly normal reabsorption of fluid and electrolytes and counteracts the dehydration so hazardous to children.

Moreover, eight years' experience has demonstrated that Lomotil controls diarrhea with a minimum of unwanted secondary actions.

Senra del Valle and his associates[1] conducted a study of 477 children with diarrhea, most of whom were hospitalized with the disorder. Lomotil, used in 407 of the children, shortened the duration of the diarrhea.

Grinszpan, Goldstein and Divito[2] used Lomotil in 20 children with diarrhea and also reported a prompt disappearance of diarrhea. Harris and Beveridge[3] in a double-blind study of 50 children with diarrhea, however, found no clear pattern to suggest that Lomotil influenced the course of the condition.

Michener, Brown and Turnbull[4] added evidence supporting the beneficial effects of Lomotil in 80 children, concluding that Lomotil was highly useful in controlling abdominal cramping, diarrhea and hypermotility.

Children: Total Daily Dosage

3-6 mo. . . . ½ tsp.* t.i.d. (3 mg.)
6-12 mo. . . ½ tsp. q.i.d. (4 mg.)
1-2 yr. . . . ½ tsp. 5 times daily (5 mg.)
2-5 yr. . . . 1 tsp. t.i.d. (6 mg.)
5-8 yr. . . . 1 tsp. q.i.d. (8 mg.)
8-12 yr. . . . 1 tsp. 5 times daily (10 mg.)
Adults: . . . . 2 tsp. 5 times daily (20 mg.) or 2 tablets q.i.d.

*Based on 4 cc. per teaspoonful.

Maintenance dosage may be as low as one-fourth the initial daily dosage.

The Bonn University and Minnesota Medicine

THIS ISSUE OF MINNESOTA MEDICINE was contributed by the faculty of the Medical School of the University of Bonn, West Germany. During the childhood of the senior members of the Board of Editors of this journal a period of postgraduate study abroad preferably at a German language school was de rigueur for the promising young medical graduate of the United States. This custom has diminished somewhat, although physicians continue to visit in Central Europe nowadays as tourists. With this issue readers of MINNESOTA MEDICINE can learn what is going on in Bonn without making the grand tour. We thank the University of Bonn, its medical school, and particularly those members of its faculty who have contributed to make this a notable issue of MINNESOTA MEDICINE.

The Board of Editors

AMA

22ND CLINICAL CONVENTION

MIAMI BEACH

DECEMBER 1-4, 1968 · CONVENTION HALL

. . . the American "Riviera." Where glittering luxury hotels tower above glamorous Collins Avenue; and medicine, sea and sunshine mix in a delightful subtropical setting.

Register now, and be on hand for the world's largest winter medical meeting—the AMA's 22nd Clinical Convention. At this midwinter "summer" session in medicine there will be Three Postgraduate Courses: Fluid and Electrolyte Balance, Diabetes, and Hyperthyroidism in the Elderly Patient • 17 Scientific Sessions • Breakfast Roundtable Conferences • Color Television • and Medical Motion Pictures. The modern, air-conditioned Convention Hall will house hundreds of scientific and industrial exhibits to show you the very latest in equipment, services and drugs.

Plan now to join your colleagues in Miami Beach. Be sure to look for the complete scientific program, plus forms for advance registration and hotel accommodations in the October 21st issue of JAMA.

Portacaval Shunt

THERE IS GENERAL agreement that portacaval anastomosis substantially reduces the risk of hemorrhage from esophageal varices in patients with cirrhosis and portal hypertension. This has been supported by the data of many investigators in both controlled and uncontrolled studies. Unfortunately, despite nearly 25 years of experience with the procedure, it is not possible to predict whether a patient can be expected to live longer with surgery than without.

In a compelling plea for "properly randomized, well-documented investigations," Grace, Muench and Chalmers[1] pointed out the lack of reliable data. They reviewed 65 papers and classified them according to the degree of control and the degree of enthusiasm for the operation. Their results indicated a striking inverse correlation between the enthusiasm of the authors and the control used in the study.

In the past few years some prospective, adequately controlled studies have been initiated, and some results are available. The results are most helpful in the case of the portacaval shunt in patients with varices but with no history of bleeding: the prophylactic shunt.

In 1965, preliminary results of a cooperative study conducted in twelve Veterans Administration Hospitals were published[2]. The investigation was prospective and randomized, and the results indicated no increase in survival over a period of up to three years when the 39 patients operated prophylactically were compared with their unoperated controls.

Conn and Lindemuth[3] published the most recent results of their prospective controlled study of the effect of prophylactic shunt on the survival of 68 cirrhotic patients. During the period of followup, up to nine years, the survival was greater in the unoperated control patients despite a greater frequency of bleeding from varices. The usefulness of prophylactic shunt in a subgroup of these patients who can be identified as undergoing greater risk of hemorrhage—those with ascites—may be of value; but the results have not as yet been published.

The data is scantier but more promising in the case of *therapeutic* portacaval shunt, in accord with the conclusions of Drs. Gütgemann and Esser in this issue of MINNESOTA MEDICINE.* The Veterans Administration cooperative group studied 39 patients who received a portacaval shunt after an initial hemorrhage from varices. After six months the survival probability was similar in the operated and control patients, and by two years the operated group showed a greater survival. Within the shunt group, the patients with hepatomegaly fared somewhat better than those without.

Certainly the available data is not conclusive, but it forms the basis for a tentative set of guidelines in the clinical management of a difficult problem. First, prophylactic surgery does not seem advisable in the unselected cirrhotic with varices, but it may prove to be of value in cases with an increased risk of bleeding, such as patients with ascites. And second, operation may prolong life, on the average, in patients who have had an episode of bleeding. Hopefully, the role of portacaval anastomosis in the therapy of the patient with esophageal varices will be clarified in the next several years.

No injection after all!

This penicillin produces high, fast levels—orally.

Pen•Vee® K is usually so rapidly and completely absorbed that therapeutic penicillin levels are attained within 15 to 30 minutes. Thus it can often obviate the need for penicillin injections. The higher serum levels produced generally last longer than with those of oral penicillin G.

Indications: Infections susceptible to oral penicillin G: prophylaxis and treatment of streptococcal infections; treatment of pneumococcal, gonococcal, and susceptible staphylococcal infections; prophylaxis of rheumatic fever in patients with a previous history of the disease.
Contraindications: Infections caused by nonsusceptible organisms; history of penicillin sensitivity.
Warnings: Acute anaphylaxis (may prove fatal unless promptly controlled) is rare but more frequent in patients with previous penicillin sensitivity, bronchial asthma or other allergies. Resuscitative (epinephrine, aminophylline, pressor amines) and supportive (antihistamines, methylprednisolone sodium succinate) drugs should be readily available. Other rare hypersensitivity reactions include nephropathy, hemolytic anemia, leucopenia and thrombocytopenia. In suspected hypersensitivity, evaluation of renal and hematopoietic systems is recommended.
Precautions: In suspected staphylococcal infections, perform proper laboratory studies including sensitivity tests. If overgrowth of nonsusceptible organisms occurs (constant observation is essential), discontinue penicillin and take appropriate measures. Whenever allergic reactions occur, withdraw penicillin unless condition being treated is considered life threatening and amenable only to penicillin. Penicillin may delay or prevent appearance of primary syphilitic lesions. Gonorrhea patients suspected of concurrent syphilis should be tested serologically for at least 3 months. When lesions of primary syphilis are suspected, dark-field examination should precede use of penicillin. Treat beta-hemolytic streptococcal infections with full therapeutic dosage for at least 10 days to prevent rheumatic fever or glomerulonephritis. In staphylococcal infections, perform surgery as indicated.
Adverse Reactions: (Penicillin has significant index of sensitization): Skin rashes, ranging from maculopapular eruptions to exfoliative dermatitis; urticaria; serum sickness-like reactions, including chills, fever, edema, arthralgia and prostration. Severe and often fatal anaphylaxis has been reported (see "Warnings").
Composition: Tablets—125 mg. (200,000 units), 250 mg. (400,000 units), 500 mg. (800,000 units); Liquid—125 mg. (200,000 units) and 250 mg. (400,000 units) per 5 cc.

Difficulties in the Diagnosis of Hypernephroma

It has been said that "to know syphilis is to know medicine." It may be said, with equal verity, that "to know hypernephroma is to know medicine." Like syphilis, hypernephroma may mimic many diffreent diseases and deserves the title, "the great imitator." Kiely and more recently Vahlensieck and St. Gödde* have pointed out that the classic triad of loin pain, flank mass, and gross hematuria are late manifestations of the disease and are not commonly noted by the internist examining patients who eventually are proved to have a renal neoplasm.

Hypernephroma may produce a wide variety of hormonal and systemic syndromes that are unrelated to the primary growth or the development of metastasis. Thus the outstanding manifestations of hypernephroma may be such nonspecific laboratory abnormalities as anemia, elevated sedimentation rate, and increased formation of rouleaux in asymptomatic patients. On the other hand, overproduction of red blood cells in cases of hypernephroma, as a result of the production of increased amounts of erythropoietin by the kidney, may lead the clinician to consider polycythemia vera. Likewise, even in the absence of hepatic metastasis, hypernephroma may cause abnormal results of liver function tests, which may revert to normal after nephrectomy. Similarly, the chief manifestation of hypernephroma may be fever of obscure origin, polyneuropathy, hypercalcemia, amyloidosis, or such nonspecific general systemic symptoms as night sweats, fatigue, and loss of weight.

It should be pointed out that, fortunately, there are few if any internal organs that can be studied as intimately as the kidney by clinical means. Excretory urography with its refinements, retrograde pyelography, nephrotomography, selective renal angiography with and without tomography, radioactive renal scans, and cytologic study of the urine are commonly employed in establishing a diagnosis of hypernephroma. Unfortunately, however, these tests may not be ordered because of the absence of suggestive signs or symptoms.

Abnormal biochemical findings such as increased levels of urinary lactic dehydrogenase and alterations in the level of urinary alkaline phosphatase have been demonstrated. It is hoped that such studies may result in a simple accurate screening test for hypernephroma.

Exercise - the Heart and the Doctor Athlete

In the July issue* Dr. Bryner of the Palo Alto Clinic presented results of a nine-year retrospective study of more than 100 physicians regarding their exercise, smoking, and dietary habits as related to the incidence of coronary artery disease among them. Conceptual arguments for regular endurance exercise as a prophylactic or therapeutic aid or both were reviewed and a plea made for further studies to confirm these beliefs.

As he noted, it is difficult to average or quantitate a person's activity level. In general, people tend to continue exercise which they found pleasurable in early years. Similarly, smoking habits were established in the young through advertising and example, a trend which the medical profession now labors to defeat, armed with large natural history studies of smokers.

As we learn more about alterations of risk factors through exercise, we can more comfortably and realistically advise our patients, with or without coronary heart disease.

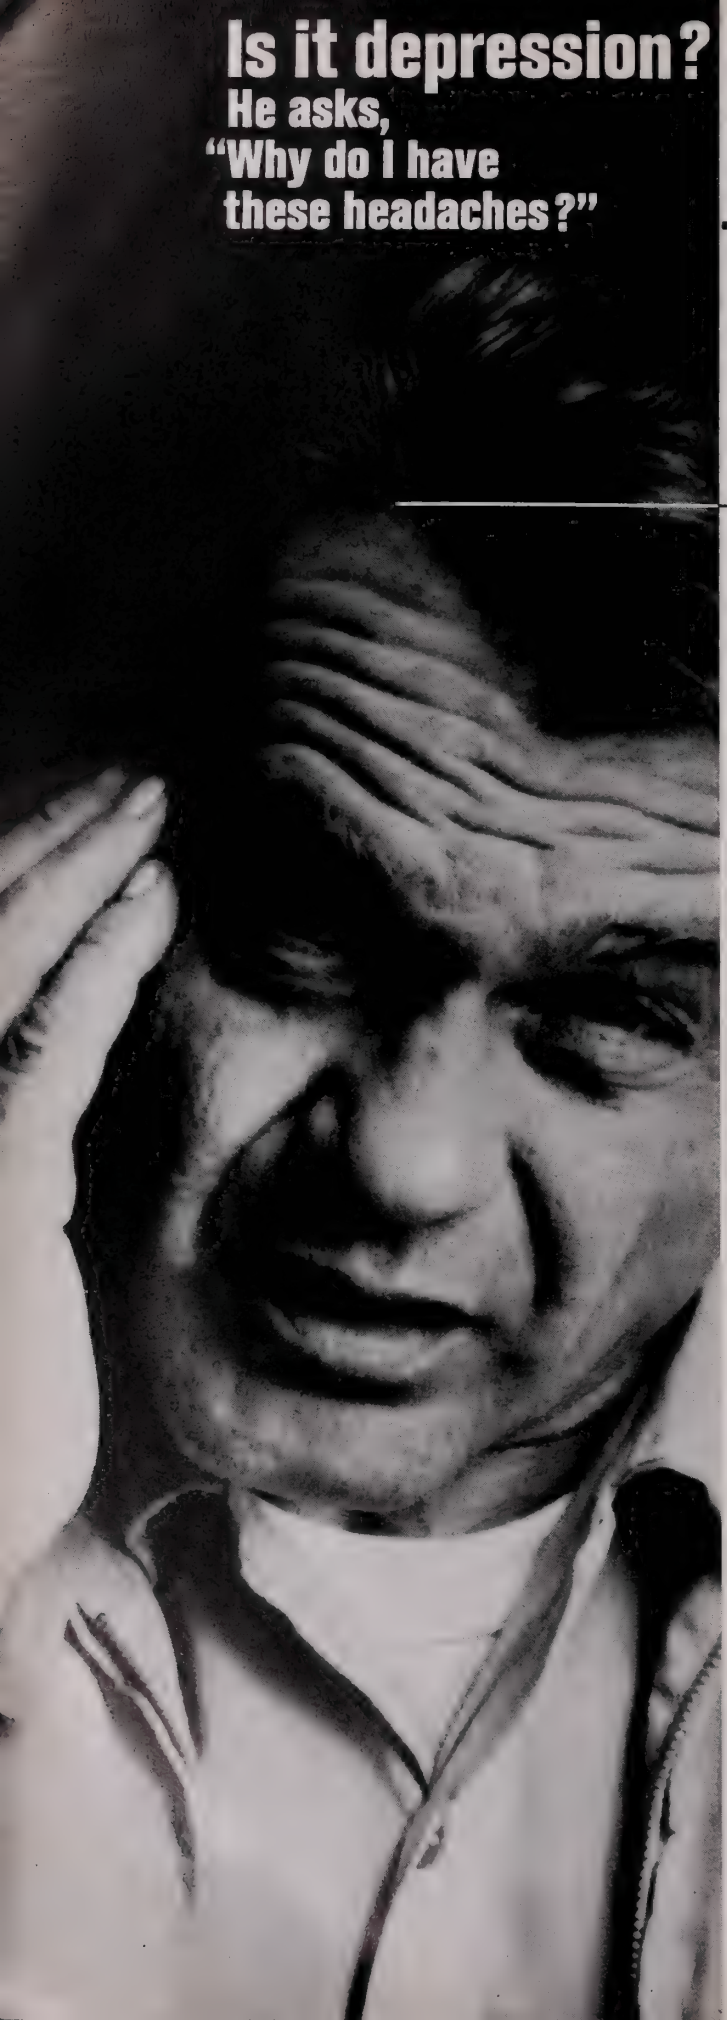
Fibrinolysis, Surgery and Euglobulin Clot Lysis

Doctors S. Wuelfing and P. B. Brandau* in their studies of fibrinolytic activity during the postoperative period did not find any significantly increased fibrinolysis as measured by the euglobulin clot lysis technic. In fact, it appears that their 47 patients had very few hemorrhagic complications. This is in agreement with the observation that postoperative hemorrhages are rarely due to excessive activation of the fibrinolytic system alone.

Instead of physiologic or depressed fibrinolysis the surgeon is usually concerned that excess fibrinolysis may be responsible for hemorrhage. Generally, fibrinolysis is not an isolated event or disease process. More commonly, hemorrhagic states are due to various combinations of abnormalities of blood vessels, including the unligated vessel, platelets and blood-clotting factors. In some cases fibrinolysis contributes to the hemorrhagic disorder.



The fibrinolytic system consists of a proenzyme (plasminogen or profibrinolysin) which can be converted to a proteolytic enzyme (plasmin or fibrinolysin) by blood and tissue activators, or iatrogenically with streptokinase or urokinase. Pathologic fibrinolysis occurs when activator(s) and the subsequently generated plasmin levels exceed their respective available inhibitors. When inhibitor levels are exceeded a state of hyperplasminemia exists. Much of our information on the effects of hyperplasminemia comes from iatrogenically induced fibrinolysis with streptokinase or urokinase. The coagulation disorder that occurs in such situations is characterized by a reduced fibrinogen level, a prolonged 1-stage prothrombin time, anti-thrombin activity, decreased factor V levels, decreased platelet adhesiveness to glass, delayed clotting in fibrinogen assays, and an altered appearance to clots. With the exception of reduced factor V levels the rest of the abnormalities are due to the products of fibrinogen and fibrin proteolysis by plasmin. The proteolysis products may be thought of as circulating anticoagulants which inhibit normal fibrin polymerization, and interfere with platelet function. When plasma contains large amounts of these proteolysis products, a 1-stage protime or thrombin clot time is a rapid way of suspecting their presence. However, with the exception of iatrogenically induced fibrinollysis or the very unusual occurrence of "primary" fibrinolysis, these tests are rarely abnormal solely because of proteolysis products.

It is important to keep in mind the role played by the liver. The liver is an important second line of defense against excess activator(s) and perhaps plasmin. The normal liver appears capable of clearing activator(s) in a few minutes. The liver also participates in the clearance of proteolysis products. Unlike activator this takes several hours. A liver whose function is compromised may prolong the effects of activator and the anticoagulant effects of proteolysis products. It can be appreciated that a burst of activator triggering the conversion of plasminogen to plasmin may be missed by assay systems if clearance mechanisms are efficient.

Euglobulin Clot Lysis

The interpretation of results of the euglobulin clot lysis technic deserves special comment. The recovery of euglobulins from plasma eliminates inhibitors of activator and plasmin. The essential potential components of euglobulin are activator, plasmin, plasminogen and fibrinogen. The substrate for lysis is the patient's own fibrinogen. Fibrinogen recovery from plasma varies from 50% to 60% and plasminogen recovery from 80% to 90%. Maximum recovery of fibrinogen and plasminogen occur at different pH's. The quantity of fibrinogen lysed depends on the quantity of plasmin present either as plasmin related to hyperplasminemia *in vivo* or as a result of activator conversion of plasminogen to plasmin *in vitro*. Therefore, the ultimate clot lysis will depend on the quantity of fibrinogen and the relative concentrations of activator, plasminogen and plasmin. The test does not discriminate between activator and

*See page 1503.

Is it depression?

He asks, "Why do I have these headaches?"

...but his other symptoms: functional somatic complaints, anxiety, insomnia, loss of interest, anorexia, feelings of guilt strongly suggest an underlying depression.

when the diagnosis is depression

ELAVIL® HCl
(AMITRIPTYLINE HCl | MSD)

Indications: Mental depression and mild anxiety accompanying depression.

Contraindications: Glaucoma and predisposition to urinary retention. Not recommended in pregnancy.

Precautions and Side Effects: Drowsiness may occur within the first few days of therapy. Patients should be warned against driving a car or operating machinery or appliances requiring alert attention. When depression is accompanied by anxiety or agitation too severe to be controlled by ELAVIL HCl alone, a phenothiazine tranquilizer may be given concomitantly. Suicide is always a possibility in mental depression and may remain until significant remission occurs. Supervise patients closely in case they may require hospitalization or concomitant electroshock therapy. Untoward reactions have been reported after the combined use of antidepressant agents having varying modes of activity. Accordingly, consider possibility of potentiation in combined use of antidepressants. Monoamine oxidase inhibitor drugs may potentiate other drugs and such potentiation may even cause death; permit at least two weeks to elapse between administration of these agents; in such patients, initiate therapy with ELAVIL HCl cautiously with gradual increase in dosage required to obtain a satisfactory response. Caution patients about errors of judgment due to change in mood, and that the response to alcohol may be potentiated. May provoke mania or hypomania in manic-depressive patients.

Side effects include drowsiness; dizziness; nausea; excitement; hypotension; fine tremor; jitteriness; weakness; headache; heartburn; anorexia; increased perspiration; incoordination; allergic-type reactions manifested by skin rash, swelling of face and tongue, itching; numbness and tingling of limbs, including peripheral neuropathy; activation of schizophrenia which may require phenothiazine tranquilizer therapy; epileptiform seizures in chronic schizophrenics; temporary confusion, disturbed concentration or, rarely, transient visual hallucinations on high dosage; evidence of anticholinergic activity, such as tachycardia, dryness of the mouth, blurring of vision, urinary retention, constipation; paralytic ileus; jaundice; agranulocytosis.

Careful observation of all patients is recommended. The antidepressant activity may be evident within 3 or 4 days or may take as long as 30 days to develop adequately, and lack of response sometimes occurs. Response to medication will vary according to severity as well as type of depression present. Elderly patients and adolescents can often be managed on lower dosage levels.

Supplied: Tablets containing 10 mg., 25 mg., and 50 mg. amitriptyline HCl, bottles of 100 and 1000; for intramuscular use, 10-cc. vials containing per cc.: 10 mg. amitriptyline HCl, 44 mg. dextrose, and methylparaben 1.5 mg. and propylparaben 0.2 mg. added as preservatives.

For more detailed information, consult your Merck Sharp & Dohme representative or see the package circular.

MERCK SHARP & DOHME Division of Merck & Co. Inc. West Point Pa. 19

WHERE TODAY'S THEORY IS TOMORROW'S THERAP

plasmin although most clinical fibrinolytic states as measured by this test are due to activator and correlate best with other more specific assays of activator. If activator is being sought, the rapid clearance mechanisms of the liver make timing of blood sampling a critical and unpredictable undertaking. In chronic situations this is probably of less importance but may introduce unpredictable variations. The addition of epsilon-amino caproic acid to the test system, to a final concentration of 10^{-4}M, will block activator but not plasmin action. This will allow separate estimates of activator and plasmin activity in the euglobulin sample.

The use of the euglobulin lysis technic alone to study the postoperative period is insufficient. The hypothesis that there is a period of depressed fibrinolytic activity is open to other interpretations. The period of postoperative hemorrhage and/or depressed or excessive fibrinolysis will require further studies of the multiple components of the fibrinolytic system, the effect of changing fibrinogen levels due to alterations in production, factors of stress, inflammation, and interrelationships with platelet function and blood coagulation.

The impression that there is excessive fibrinolytic activity in a patient must be supported by adequate laboratory testing and cannot be left to intuition. The use of powerful drugs to block fibrinolytic activity carries the risk of depressing a physiologic activation of the clot lysis system in circumstances of excessive clot formation. This may result in massive widespread thrombosis.

Sulfobromophthalein Test

THE SULFOBROMOPHTHALEIN test is the single most valuable liver function test. It fulfills the four criteria for a good function test, namely: it effectively differentiates normal from abnormal; it distinguishes various grades of abnormality; it contributes information not already available from a simpler test; it is technically simple. In the light of its overwhelming value and considering the millions of doses of the drug which have been given, the incidence of 32 anaphylactoid reactions, including 14 fatalities, is an acceptable risk. Shafer and Gregory* in a previous issue have indicated the precautions necessary to reduce the chance of a serious reaction, namely: preparation of a possible acute anaphylactoid reaction and prohibition of this dye's use in patients with an allergic or asthmatic history.

The incidence of the less serious side reactions such as faintness, chills, injection discomfort can be decreased by diluting the drug and by slow administration over a period of five minutes. The manufacturer has insisted on putting the dye out in a concentrated convenient form at the expense of some increase in side effects. Recent work indicates that another dye, Indocyanin Green, which is used clinically for cardiac output at present, is just as valid as a hepatic function test as sulfobromophthalein and is safer. Its expense is a bar to general usage, however.

Sulfobromophthalein measures mainly circulatory factors of hepatic function. Inflammatory reaction is measured best by the zinc turbidity or the cephalin-cholesterol flocculation test. The alkaline phosphatase is the best test for regurgitation or biliary obstruction. The transaminase test is the best measure of hepatic cell necrosis. The urinary hippuric acid reaction and coproporphyrin are excretory tests which measure liver function, but these are more difficult in their administration or as a laboratory procedure. As a single test of liver function, the sulfobromophthalein ranks as the best.

...soothes colicky pain with paregoric*
...consolidates fluid stools with pectin
...adsorbs irritants with kaolin,
and protects intestinal mucosa

Whether it's a 24-hour "bug", a food problem, or simply nervousness and anxiety, Parepectolin will bring the diarrhea under control until etiology can be determined. In some cases, Parepectolin may be all the therapy necessary.

Parepectolin®

Each fluid ounce of creamy white suspension contains:
*Paregoric (equivalent) ..... (1.0 dram) 3.7 ml.
Contains opium (¼ grain) 15 mg. per fluid ounce.
warning: may be habit forming
Pectin ..... (2½ grains) 162 mg.
Kaolin (specially purified) .... (85 grains) 5.5 Gm.
(alcohol 0.69%)
Usual Adult Dose: One or two tablespoonfuls three times daily.
Usual Children's Dose: One or two teaspoonfuls three times daily.

Marinesco-Sjögren Syndrome

THE RARE SYNDROME originally described in 1931 by Marinesco and collaborators[1] as a "familial disease characterized by congenital cataracts and retarded somato-neuro-psychic development" includes muscle wasting and is of a progressive nature as observed by them and later by Sjögren.[2] Drs. Alter and Kennedy present an additional patient[3] and provide further evidence of an accompanying myopathic process as evidenced by electromyographic findings and increase of serum creatinine phosphokinase. The Marinesco-Sjögren syndrome affects many tissues of ectodermal or mesodermal origin. It is inherited as an autosomal recessive disorder and probably represents an inborn error of metabolism whose exact biochemical nature remains to be determined.

You May Be Right

The General Practitioner

THE ROLE of the "primary physician" of the Millis Report and the "family physician" of Dr. Caughey's report would not have inspired me to enter medicine.

Dr. Caughey tells us that the American Medical Association's ad hoc Committee believes that a "well-trained family physician with a continuing relationship with the individual patient is the best qualified person to make a comprehensive examination, guide the patient in the use of available resources and carry through a program to meet his long-term needs." But when does he find time to treat the patient? And if the role of the family physician is to insure that "there must be much more attention paid to health maintenance and preventive medicine," must he not assume the role of county nurse and social worker to the exclusion of his role as a doctor?

The general practice which I know is vital. It is an indispensable service. It is a total commitment. And in my own practice, many patients would have expired if I had been only a primary physician, for the closest specialty practice is 100 miles away.

There was the six-year-old asthmatic boy, with ruptured spleen, comatose, in shock, needing an immediate splenectomy; there was the man with high velocity deer-rifle wounds with massive hemorrhage, the woman with severe post-partum hemorrhage, requiring immediate hysterectomy. There was the man with half his frontal lobe missing, who was brought to our hospital in a sleet storm when the ambulance could not continue to the intended specialist 160 miles away. There were untold numbers of farm accidents, car accidents and acute surgical problems. These have all been cared for by me, with either a physician assistant or good nurse assistance. We have had no maternal deaths, and have had uniformly good results with a wide spectrum of general surgery and orthopedics.

The Millis Report states: "The general practitioner of revered memory . . . is vanishing . . . he leaves behind a vacuum that organized medicine has not decided how to fill."

Something is being done. Training to be a general practitioner is a lifetime endeavor; I have attended refresher courses at the Cleveland Clinic, the University of Minnesota Medical School short courses and continuation courses, plus regional and state AAGP meetings and seminars. I maintain a library of current medical books and journals.

It is my contention that 90 per cent of the patient's ills can be cared for by a well-trained, conscientious general practitioner, but organized medicine seems to be most concerned with the remaining ten per cent of obscure and complicated diseases. And it seems to me that the proposed primary physician would serve as a shuttle service rather than as a physician who treats the patient.

I believe that general practice involves total commitment of the physician, total care of the patient (often spiritual and psychological as well as medical). General practice offers for me an ideal situation in that I enjoy close proximity of home to office, hospital and church; and because no time is lost in transportation, patients are treated immediately.

General practice means freedom for greater responsibility, not diminution of it. General practice offers every opportunity for self improvement; but surgical and orthopedic training are necessary. The rather limited content of the education of a primary physician, as proposed by the Millis Report, of medicine, psychiatry, pediatrics, medical gynecology and preventive medicine can hardly encompass comprehensive care. General practice offers stimulation for self-discipline, which requires a strong faith and constant spiritual renewal.

If the recommendations of the Millis Report are adopted, I believe it will terminate rural general practice as I know it. This is not the vision of medicine which captivated me through my medical school days under beloved and revered men such as Doctors Sollman, Wiggers, Scott, Karsner, Karnosh, and Goldblatt, to mention a few. I recall with great appreciation Dr. Karnosh's commencement address October, 1943, to the Western Reserve Medical School Graduates on "The Uncommon Man"; he was in no sense speaking of the primary physician.

Lloyd H. Klefstad, M.D.
Greenbush, Minnesota

The Editor's Soliloquy

Ein Tiger Im Tank *

A TIGER IN THE TANK, like lifting oneself by one's bootstraps, is an expression denoting the accomplishment of an exceptional and laudible feat.

This issue of MINNESOTA MEDICINE is endeavoring to start a precedent establishing international communication in medical literature. Though we live within the sphere of influence of the illustrious medical centers of the world, we are deterred by language barriers from mutual exchange of ideas. This is to our detriment; for it creates a time lag in the dissemination of many of the avant-garde ideas and achievements of eminent thinkers and doers in medical theory and practice.

True, genuine progress in any one area eventually penetrates to and is assimilated by all other areas—but only very gradually. So, with the various international exchange programs now so rapidly proliferating, we asked ourselves: Why wait for the slow diffusion of osmosis; why not initiate direct thrust and swift interchange in medical journalism as well as in other fields?

By sheer good fortune this Editor was able to make the acquaintance of an honorable, noble and far-seeing West German surgeon from the University of Bonn: Herr Professor Dr. Gütgemann, who envisioned and articulated the tremendous value accruing to the whole of medical science by establishing better and fuller international communication in medical literature. Though aware of our paucity of multi-linguality, he agreed, after the exchange of a few letters, to provide us with an entire issue of MINNESOTA MEDICINE, expounding some of the revolutionary medical advances germinating in and emanating from the valley of the Rhine.

To prepare a Special Issue of any medical journal is a task of no mean proportions: a venture that demands energy, drive, determination and authority; familiarity with a wide field of medical literature; and a keen assessment of the reading interests of subscribers.

Your Editor has had the opportunity to shake hands and visit with the author of this issue and his staff. He is proud to dedicate this issue of MINNESOTA MEDICINE to Professor Alfred Gütgemann and his able and energetic co-workers for a job singularly well done.

Carl O. Rice, M.D.
Editor-in-Chief.

In the complex picture of moderate to severe anxiety...

there is a new reason for prescribing Mellaril (Thioridazine HCl)

effectiveness in mixed anxiety-depression

Long recognized for its usefulness in the treatment of moderate to severe anxiety, Mellaril is now also known to be effective against mixed anxiety-depression.

Often the symptoms of anxiety states are difficult to sort out—even with the most careful probing. The patient may manifest symptoms of agitation, restlessness, insomnia, somatic complaints. But what of the depression that may be mixed in the total picture? It is reassuring to know that Mellaril may be prescribed—with strong possibilities of success—when there is anxiety alone or a mixture of anxiety and depression.

Before prescribing or administering, see Sandoz literature for full product information, including adverse reactions reported with phenothiazines. The following is a brief precautionary statement.

Contraindications: Severe central nervous system depression, comatose states from any cause, hypertensive or hypotensive heart disease of extreme degree.

Warnings: Administer cautiously to patients who have previously exhibited a hypersensitivity reaction (e.g., blood dyscrasias, jaundice) to phenothiazines. Phenothiazines are capable of potentiating central nervous system depressants (e.g., anesthetics, opiates, alcohol, etc.) as well as atropine and phosphorus insecticides. During pregnancy, administer only when necessary.

Precautions: There have been infrequent reports of leukopenia and/or agranulocytosis and convulsive seizures. In epileptic patients, anticonvulsant medication should also be maintained. Pigmentary retinopathy may be avoided by remaining within the recommended limits of dosage. Administer cautiously to patients participating in activities requiring complete mental alertness (e.g., driving). Orthostatic hypotension is more common in females than in males. Do not use epinephrine in treating drug-induced hypotension. Daily doses in excess of 300 mg. should be used only in severe neuropsychiatric conditions.

Adverse Reactions: *Central Nervous System*—Drowsiness, especially with large doses, early in treatment; infrequently, pseudoparkinsonism and other extrapyramidal symptoms; nocturnal confusion, hyperactivity, lethargy, psychotic reactions, restlessness, and headache. *Autonomic Nervous System*—Dryness of mouth, blurred vision, constipation, nausea, vomiting, diarrhea, nasal stuffiness, and pallor. *Endocrine System*—Galactorrhea, breast engorgement, amenorrhea, inhibition of ejaculation, and peripheral edema. *Skin*—Dermatitis and skin eruptions of the urticarial type, photosensitivity. *Cardiovascular System*—Changes in the terminal portion of the electrocardiogram have been observed in some patients receiving the phenothiazine tranquilizers, including Mellaril (thioridazine hydrochloride). While there is no evidence at present that these changes are in any way precursors of any significant disturbance of cardiac rhythm, several sudden and unexpected deaths apparently due to cardiac arrest have occurred in patients previously showing electrocardiographic changes. The use of periodic electrocardiograms has been proposed but would appear to be of questionable value as a predictive device. *Other*—A single case described as parotid swelling.

Mellaril®
(Thioridazine HCl)
25 mg. t.i.d.

for moderate to severe anxiety and mixed anxiety-depression

SANDOZ SANDOZ PHARMACEUTICALS, HANOVER, N. J. 68-170

Louie lost weeks with acute shoulder bursitis. That's a l
of pain, stiffness and tenderness...and also a lot of fis
It might have been different with **Butazolidin® alk**

100 mg. phenylbutazone
100 mg. dried aluminum hydroxide gel
150 mg. magnesium trisilicate

If it doesn't work in a week, forget

But please don't forget this:

Contraindications: Edema; danger of cardiac decompensation; history or symptoms of peptic ulcer; renal, hepatic or cardiac damage; history of drug allergy; history of blood dyscrasia. The drug should not be given when the patient is senile or when other potent drugs are given concurrently. Large doses of the alka formulation are contraindicated in glaucoma.

Warning: If coumarin-type anticoagulants are given simultaneously, watch for excessive increase in prothrombin time. Instances of severe bleeding have occurred. Persistent or severe dyspepsia may indicate peptic ulcer; perform upper gastrointestinal x-ray diagnostic tests if drug is continued. Pyrazole compounds may potentiate the pharmacologic action of sulfonylurea, sulfonamide-type agents and insulin. Carefully observe patients receiving such therapy. Use with caution in the first trimester of pregnancy and in patients with thyroid disease.

Precautions: Before prescribing, carefully select patients, avoiding those responsive to routine measures as well as contraindicated patients. Obtain a detailed history and a complete physical and laboratory examination, including a blood count. Patients should not exceed recommended dosage, should be closely supervised and should be warned to discontinue the drug and report immediately if fever, sore throat, or mouth lesions (symptoms of blood dyscrasia); sudden weight gain (water retention); skin reactions; black or tarry stools or other evidence of intestinal hemorrhage occur. Make complete blood counts at weekly intervals during early therapy and at 2-week intervals thereafter. Discontinue the drug immediately and institute countermeasures if the white count changes significantly, granulocytes decrease, or immature forms appear. Use greater care in the elderly and in hypertensives.

Adverse Reactions: The more common are nausea and edema. Swelling of the ankles or face may be minimized by withholding dietary salt, reduction in dosage or use of diuretics. In elderly patients and in those with hypertension the drug should be discontinued with the appearance of edema. The drug has been associated with peptic ulcer and may reactivate a latent peptic ulcer. The patient should be instructed to take doses immediately before or after meals or with milk to minimize gastric upset. Drug rash occasionally occurs. If it does, promptly discontinue the drug. Agranulocytosis, exfoliative dermatitis, Stevens-Johnson syndrome, Lyell's syndrome (toxic necrotizing epidermolysis), or a generalized allergic reaction similar to serum sickness may occur and require permanent withdrawal of medication. Agranulocytosis can occur suddenly in spite of regular, repeated normal white counts. Stomatitis, salivary gland enlargement, vomiting, vertigo and languor may occur. Leukemia and leukemoid reactions have been reported. While not definitely attributable to the drug, a causal relationship cannot be excluded. Thrombocytopenic purpura and aplastic anemia may occur. Confusional states, agitation, headache, blurred vision, optic neuritis and transient hearing loss have been reported, as have hyperglycemia, hepatitis, jaundice, hypersensitivity angiitis, pericarditis and several cases of anuria and hematuria. With long-term use, reversible thyroid hyperplasia may occur infrequently. Moderate lowering of the red cell count due to hemodilution may occur.

Dosage in Painful Shoulder: Initial: 3 to 6 capsules daily in 3 or 4 equal doses. Trial period: 1 week. Maintenance dosage should not exceed 4 capsules daily; response is often achieved with 1 or 2 capsules daily.

In selecting the appropriate dosage in any specific case, consideration should be given to the patient's weight, general health, age and any other factors influencing drug response.

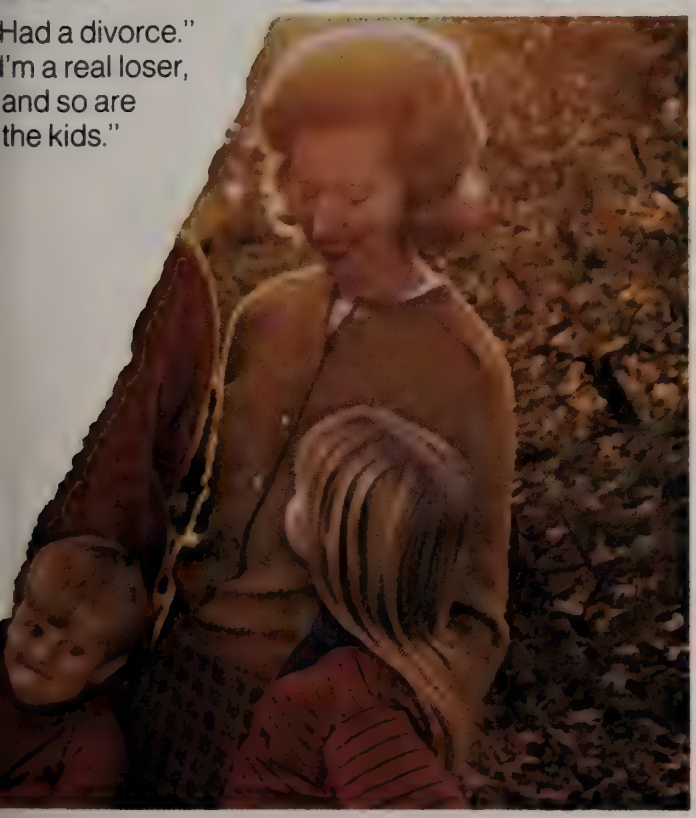
The Divorced Depressive: "Forty, Forgotten



"Had a large wedding."
"Had a fine home and family."

TO-5757

.Forlorn"

Had a divorce."
I'm a real loser,
and so are
the kids."

in depression

The loss of marital compatibility results in nearly 500,000 U.S. divorces each year.

Depression characterized by untold guilt feelings, grief and loneliness may follow.

When you diagnose depression, Tofrānil may be indicated for relief.

As maintenance therapy during the active phase of depression, Tofrānil can often help prevent relapse.

The use of Tofrānil in patients receiving M.A.O.I.'s is contraindicated. In patients with cardiovascular disease, thyroid disorders, increased intraocular pressure; in those receiving anticholinergics (including antiparkinsonism agents), thyroid medication or antihypertensive adrenergic neuron-blocking agents; and in those in their first trimester of pregnancy—the special precautions listed in the Prescribing Information should be carefully observed.

Toxic reactions severe enough to require discontinuation of Tofrānil are uncommon. However, for complete details, please refer to the complete Prescribing Information.

Turn page for brief summary of Prescribing Information.

Tofrānil® imipramine hydrochloride
Geigy

in depression

Tofranil® Geigy

imipramine
hydrochloride

Tofranil®, imipramine hydrochloride
Indications: Tofranil is recommended for the treatment of depressive states of diverse psychopathology.
Contraindications: The concomitant use of this agent and monoamine oxidase inhibiting (M.A.O.I.) compounds is contraindicated. Hyperpyretic crises or severe convulsive seizures may occur. Potentiation of adverse effects can be serious or even fatal. An interval of at least 7 days after M.A.O.I. therapy has been discontinued should be allowed before this drug may be substituted. Initial dosage should be low, increases should be gradual, and the patient's progress should be carefully observed.
Warning: Clinical reports have suggested that there may be a risk of teratogenesis associated with the use of this compound during the first trimester of pregnancy. Unless, in the opinion of the prescribing physician, the potential benefits outweigh the possible risks, it should not be used during the first trimester of pregnancy. Cardiovascular complications, including myocardial infarction and arrhythmias, have occasionally occurred in susceptible individuals. Patients with cardiovascular disease should be given the drug only under careful observation and in low dosage.
Precautions: Since suicide is always a possibility in severely depressed patients and one which may persist until significant remission occurs, such patients should be carefully supervised during early treatment. Some severely depressed patients may also require hospitalization and/or concomitant electroconvulsive therapy. Because of its anticholinergic effect, caution should be observed in prescribing the drug for patients with increased intraocular pressure.
In rare instances, transient cardiac arrhythmias have occurred in hyperthyroid patients and in patients receiving thyroid medication when this compound was added to the regimen. Imipramine may block the pharmacologic activity of guanethidine and other related adrenergic neuron-blocking agents.
The drug is not recommended at the present time in patients under 12 years of age.
Adverse Reactions: Dryness of the mouth, tachycardia, constipation, disturbances of accommodation, sweating, dizziness, weight gain, urinary frequency or retention, nausea and vomiting, peripheral neuritis, mild parkinson-like syndrome, tremors, rare cases of falling in elderly patients, confusional states (with such symptoms as hallucinations and disorientation), activation of psychosis in schizophrenics and agitation (including hypomanic and manic episodes) which may require dosage reduction and/or addition of a tranquilizer or temporary discontinuation of the drug, epileptiform seizures, orthostatic hypotension and substantial blood pressure fall in hypertensive patients, purpura, transient jaundice, bone marrow depression including agranulocytosis, sensitization and skin rash including photosensitization, eosinophilia, and mild withdrawal symptoms on sudden discontinuation after prolonged treatment with high doses. Occasional hormonal effects (impotence, decreased libido, and estrogenic effects) may be observed. Atropine-like effects may be more pronounced (e.g. paralytic ileus) in susceptible patients and in those using anticholinergic agents (including antiparkinsonism drugs).
Outpatient Adult Dosage: Initially, 75 mg. daily, increased, if necessary, to 150 or 200 mg. Maintenance dosage may be lower, 50 to 150 mg. daily, if possible.
Geriatric and Adolescent Dosage: Initially, 30 or 40 mg. daily, which may be increased according to response and tolerance. It is usually unnecessary to exceed 100 mg. daily.
A lag in therapeutic response, lasting from a few days to a few weeks, should be expected. When dosage recommendations are already being followed, increasing the dosage does not normally shorten this latency period and may increase the incidence of adverse reactions.
Availability: Round tablets of 25 and 50 mg.; triangular tablets of 10 mg. for geriatric and adolescent use; and ampuls, each containing 25 mg. in 2 cc. for I.M. administration.

Curbstone Consultation

RENAL HOMOGRAFT TRANSPLANT REJECTION

QUESTION: What drugs are used to prevent rejection in renal homograft transplants?

ANSWER: Only three agents when used alone have been shown experimentally to provide indefinite survival of renal homografts. These drugs are azathioprine, prednisone, and antilymphocyte serum. Azathioprine is the principal agent used for immunosuppression. Prednisone is the most valuable for securing reversal of acute rejection episodes. The effects produced by antilymphocyte serum are dependent on many variables. Whereas it may suppress early primary rejection it does not affect the cell already producing serum antibodies.

Harold D. Kletschka, M.D.
Houston, Texas

TILT TABLE

QUESTION: I recently heard about the use of a device called a "tilt table" in connection with the manned space program. Is such a device of any clinical value or is it strictly a research instrument?

ANSWER: Although the tilt table is often used as a research tool it has very definite clinical application as well. It is used to test the reflex regulatory mechanisms of such things as the heart, the brain, the vascular system, and the peripheral tissues of the body. This is accomplished through the measurement and evaluation of changes in the heart rate, the vasomotor tone, the blood pressure, and the tissue edema as a patient is changed from a horizontal to a vertical and then back to a horizontal position. It has also been described as a good test of the physical fitness of an individual. The Air Force and NASA use it as a test of the physical fitness of their pilots as well as to determine how well the pilots can undergo sudden and drastic changes in gravitational forces. Although it presently requires much experience to correctly interpret and evaluate the results, the knowledge that can thus be gained makes it a clinically important device.

Edson H. Rafferty B.S. (Biochem.)
Houston, Texas

Voice

The ideal voice for radio may be defined as having no substance, no sex, no owner, and a message of importance for every housewife.—Harry Wade

Nature to the Rescue

Common Duct Obstruction*

The gall bladder, too, has its own particular brand of magic. Mrs. Jemkins had been sick and jaundiced to a deep yellow tint for many years. All the clinics and doctors she had consulted, including myself, thought that she was dying of a malignant form of jaundice arising from a cancer of the liver or gall bladder. To operate would have been murder—or, if she had demanded it—suicide. I relieved her agony with opiates and waited for the end, which I hoped would come quickly and mercifully. She became thinner and thinner, and yellower and yellower, until she looked more like a museum mummy than a human being. To call upon her regularly would have been exploitation, and I was unable to do anything for her except prescribe pain-relieving remedies, and that could be done over the phone.

One day her husband asked me to come over to see her. It was generally believed that the end was near, and I expected to sign her death certificate at any hour. I was speechless when I saw the change in her from the week before. Her eyes had lost that deep bronze shade; she had taken a new lease on life. She said a great load had been lifted from her mind after something had happened to her abdomen. The nausea had left her; she suffered no pain. Of course I was suspicious at first that it was the advent of the anesthesia of death; many forlorn cases become hopeful and radiant just before the end. But she continued to improve, ate normally, gained weight, and finally became human once more. Fifteen years after she had been condemned to death, I saw her looking very well.

What had happened was that the obstruction in the common gall duct, which backed the bile up into the liver, was relieved by the gall bladder's boring a hole into the intestine, allowing the bile to reach the intestine by a different route. The inflammation in the gall bladder attached itself (called an "adhesion") to the nearest bit of intestine. A swelling began at the point of attachment; the swelling cut off the blood supply to the center of the inflammation, which died and sloughed through, making a perforation between gall bladder and intestine. The opening became larger as the inflammation subsided, and remained permanently. The cure was also permanent, as the pent-up secretions and poisons found a new and harmless outlet. Surgeons frequently copy Nature's technique; but we cannot do it when inflammation is present, because our patients would die of peritonitis. Nature beat us at that game.*

*Joseph A. Jerger: Doctor—Here's Your Hat, 1939.

There is as much healing power in a Beethoven sonata or a painting by Constable as in excerpts from the Bible.—George Bernard Shaw

I think there is only one quality worse than hardness of heart and that is softness of head.—Theodore Roosevelt

The Viewing Box

Hilar Mass and Hemoptysis in a Fifteen-Year-Old Patient

THE PATIENT, a 15-year-old athlete, developed persisting cough and occasional hemoptysis about a month before admission. His general health remained good. About 10 days before admission he had clinical and x-ray evidence of pneumonia in the right lung base which cleared, but right hilar enlargement persisted. Posteroanterior chest x-ray (Figure 1) on admission showed right superior hilar shadow enlargement.

In the hospital the patient was afebrile. There was no peripheral adenopathy. Routine laboratory data were normal. Bacteriology of throat and sputum was normal. Histoplasmin skin test was positive.

Bronchoscopy showed a polypoid mass protruding from the right upper lobe bronchus obstructing that lobe and almost obstructing the right main bronchus.

Figure 2 is a coned-down bronchographic view of the carina and right main bronchus region showing a contrast-covered mass protruding into the right main bronchus from the orifice of the right upper lobe bronchus. The trachea and carina are dotted in for orientation.

A right upper lobectomy was done. The right upper lobe bronchus was completely obstructed, but the lobe was aerated apparently by collateral ventilation.

What is your diagnosis? (See next page).

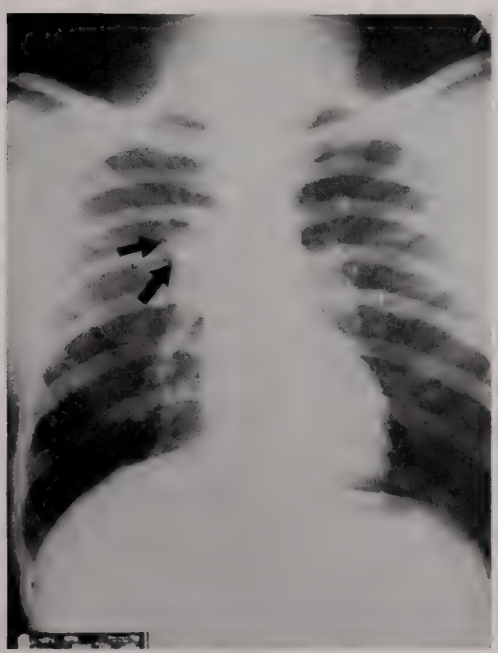

Figure 1

Figure 2

Diagnosis: The tumor was bronchial adenoma, carcinoid type, with invasion of adjacent nodes. The removed nodes also showed histoplasmosis, an unrelated coincidence.

Comment

This patient exhibited the typical clinical picture of bronchial adenoma: (1) slowly clearing or recurring pulmonary infection, (2) chronic cough, (3) hemoptysis, and (4) central pulmonary nodule or hilar mass.

Although generally an adult disease, occasional childhood cases have been reported.[1]

About 90% of the adenomas are carcinoid type histologically,[2] but the carcinoid syndrome is rare (about 2%) among pulmonary adenomas.[3,4] About half of these patients have hemoptysis, attesting to the vascularity of the tumor. Because of this vascularity, it is usually inadvisable to biopsy via the bronchoscope. This tumor has a low malignant potential, about 70% of patients of all ages surviving 10 years.[5]

Code of Hammurabi

The total Code of Hammurabi consists of 282 sections dealing with property and persons. It is strictly a civil code, containing no religious legislation whatsoever. The paragraphs quoted here comprise the totality of the Code with reference to doctors and veterinarians.

215. If a doctor has treated a gentleman for a severe wound with a bronze lancet and has cured the man, or has opened an abscess of the eye for a gentleman with the bronze lancet and has cured the eye of the gentleman, he shall take ten shekels of silver.

216. If he (the patient) be the son of a poor man, he shall take five shekels of silver.

217. If he be a gentleman's servant, the master of the servant shall give two shekels of silver to the doctor.

218. If the doctor has treated a gentleman for a severe wound with a lancet of bronze and has caused the gentleman to die, or has opened an abscess of the eye for a gentleman with the bronze lancet, and has caused the loss of the gentleman's eye, one shall cut off his hands.

219. If a doctor has treated the severe wound of a slave of a poor man with a bronze lancet and has caused his death, he shall render slave for slave.

220. If he has opened his abscess with a bronze lancet and has made him lose his eye, he shall pay money, half his price.

221. If a doctor has cured the shattered limb of a gentleman, or has cured the diseased bowel, the patient shall give five shekels of silver to the doctor.

222. If it is the son of a poor man, he shall give three shekels of silver.

223. If a gentleman's servant, the master of the slave shall give two shekels of silver to the doctor.

Fracture Conference

Fractures of the Phalanges

Mallet Finger

Dr. Daniel Boyce:*

The first patient is a 67-year-old man who caught the distal segment of his right finger in the trigger guard of a shotgun and felt a sudden snap on extricating it. The "mallet" deformity was 10 days old when he came for treatment (Figure 1 A).

Dr. Ronald Linscheid:†

In this injury a portion of the distal phalanx has fractured into the joint and is slightly displaced. The problem is the tendency for the distal phalanx to sublux volarly and for the dorsal fragment to be pulled up by the conjoined tendon, with the result that there are late degenerative changes and "mallet" finger deformity. The options are to treat this conservatively with splintage or to perform an open reduction. We elected to insert Kirschner wires into the fragment after blocking the finger with local anesthesia (Figure 1 B). There is some tendency for the dorsal fragment to work up on the Kirschner wires; to prevent this it is helpful to put them in at slight angles. It is also difficult at times to pierce this fragment unless it is especially large. Another way to hold it is with a pull-out wire through a drill hole. If one elects to treat the fracture with Kirschner wires, it helps to take a roentgenogram within a couple of days to be sure the fracture is not becoming displaced.

Epiphyseal Fracture

Dr. Boyce:

The next patient is a 27-year-old woman who was a backseat passenger when involved in an automobile accident. She raised her right hand in an effort to protect herself and sustained an injury to the little finger (Figure 2).

Dr. Linscheid:

This fracture is just above the flare of the base of the proximal phalanx

Conference held at the Mayo Clinic, Rochester, March 11, 1968.

*Resident in Orthopedic Surgery, Mayo Graduate School of Medicine (University of Minnesota), Rochester.

†Assistant Professor of Orthopedic Surgery, Mayo Graduate School of Medicine (University of Minnesota) and Consultant, Section of Orthopedic Surgery, Mayo Clinic, Rochester.

of the little finger and is deviated ulnarly and dorsally. It is analogous to the fractures seen in children that are type II epiphyseal injuries, in which the finger is also in ulnar deviation and is dorsally displaced. The reason we elected to show this method of treatment with the use of a flexed aluminum splint incorporated in a gauntlet cast is that the splint is not bent enough. The finger was in only slight flexion. The splint should be bent back on itself so that the immobilized fingertip is pointing at the tuberosity of the scaphoid.

Dr. Richard S. Bryan:*

In the epiphyseal fractures in this area in young children, a ballpoint pen fits nicely into the web space between the metacarpal heads, and the fracture can be reduced with minimal force by squeezing the fingers together. It's a

*Consultant, Section of Orthopedic Surgery, Mayo Clinic, Rochester.

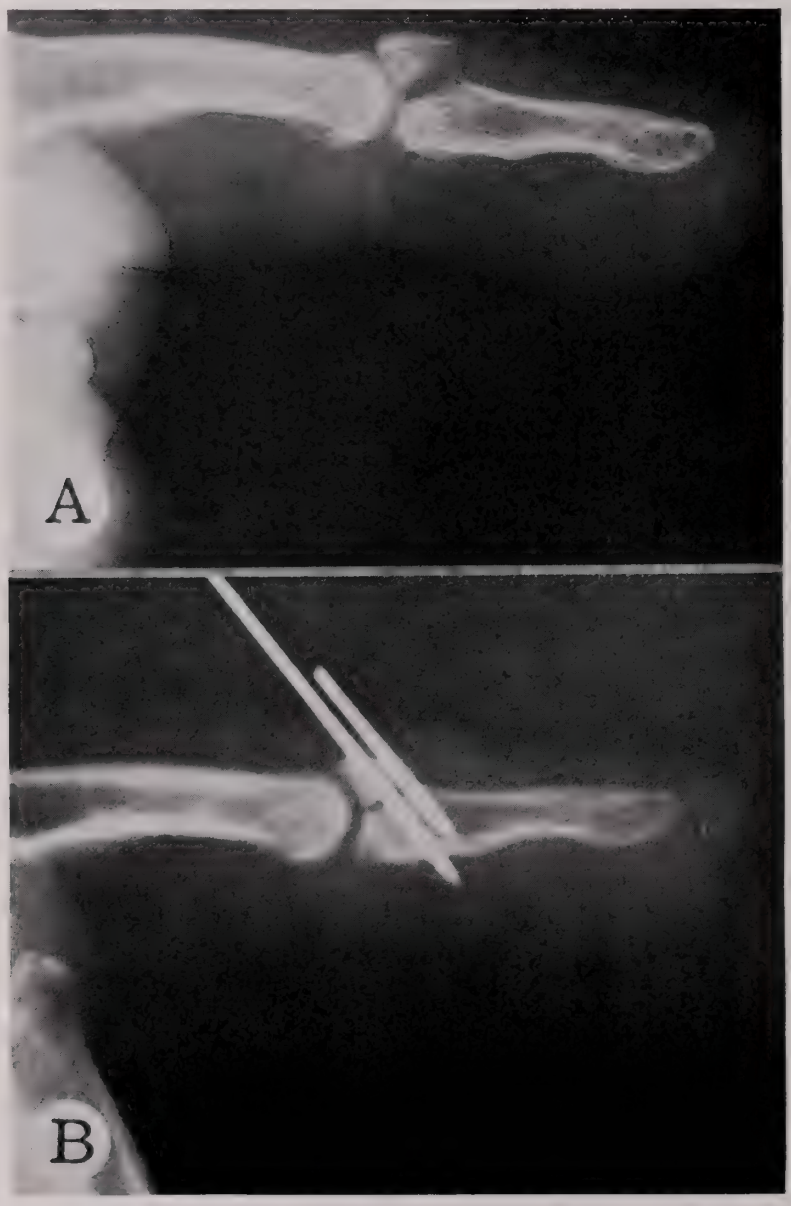

Fig. 1 *(A)*—Intra-articular avulsion fracture of distal phalanx associated with "mallet" finger. *(B)* Fixation with Kirschner wires.

neat trick.

Dr. Mark B. Coventry:*

How would you prefer to immobilize such a fracture once it has been reduced?

Dr. Linscheid:

I think it is difficult to hold because it tends to return into ulnar deviation. I have been using a gauntlet cast with an aluminum (Alumnafoam) splint.

Dr. Bryan:

What would be wrong with taping this finger to the ring finger and allowing the ring finger to act as a mobile splint?

Dr. Linscheid:

That should be quite satisfactory for this fracture.

Dr. Boyce:

The next case is that of an eight-year-old boy who injured his long finger.

Dr. Linscheid:

We didn't know how he injured his finger, but the deformity was obvious (Figure 3). There is a proximal phalangeal fracture with volar angulation at the fracture site (Figure 4-A). Is this a typical position for this fracture to assume?

Dr. Sherwin Goldman:†

It seems it would occur the other way, the flexors being stronger.

Dr. Linscheid:

The flexors are stronger. Can you think of any other reason why a typical deformity might occur in this direction rather than be dorsally angulated?

---

†Resident in Orthopedic Surgery, Mayo Graduate School of Medicine (University of Minnesota), Rochester.

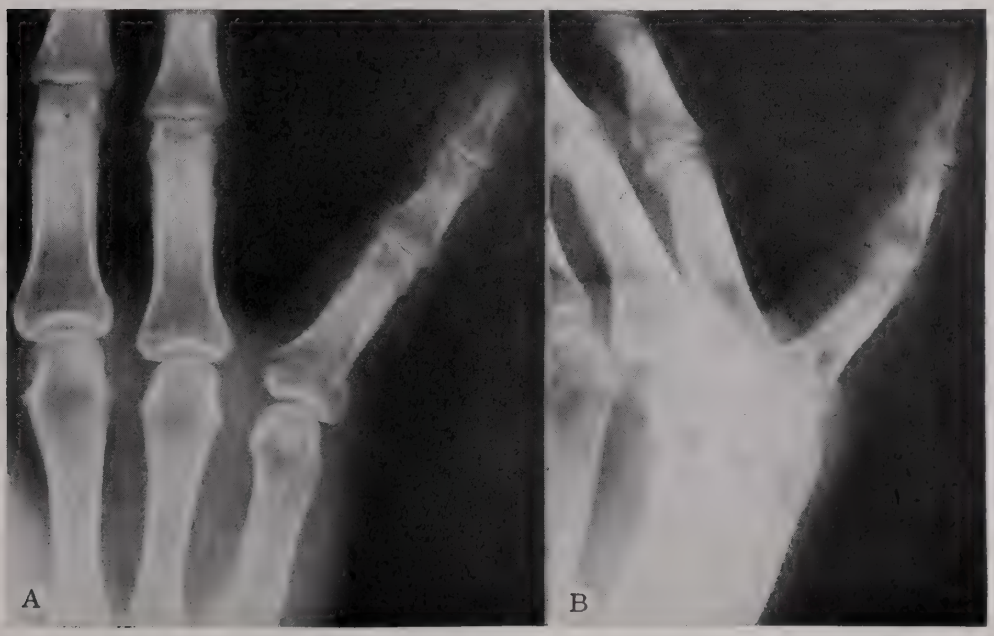

Fig. 2 *(A)*—Anteroposterior view of fracture of proximal phalanx of fifth finger, showing ulnar deviation at fracture site. *(B)* Lateral view demonstrates dorsal angulation at fracture site.

Dr. Goldman:

The extensor hood, particularly the pull of the lumbrical muscles.

Dr. Linscheid:

The extensor hood forms a sling over this area of the proximal phalanx. The wing tendons and the lateral bands come up in an oblique direction and connect with the central slip through oblique fibers. The flexor superficialis attaches at the proximal third of the middle phalanx so that, although the flexors are stronger than the extensors, because of the interposed joint and the anatomy of the extensor apparatus this is the typical deformity for a

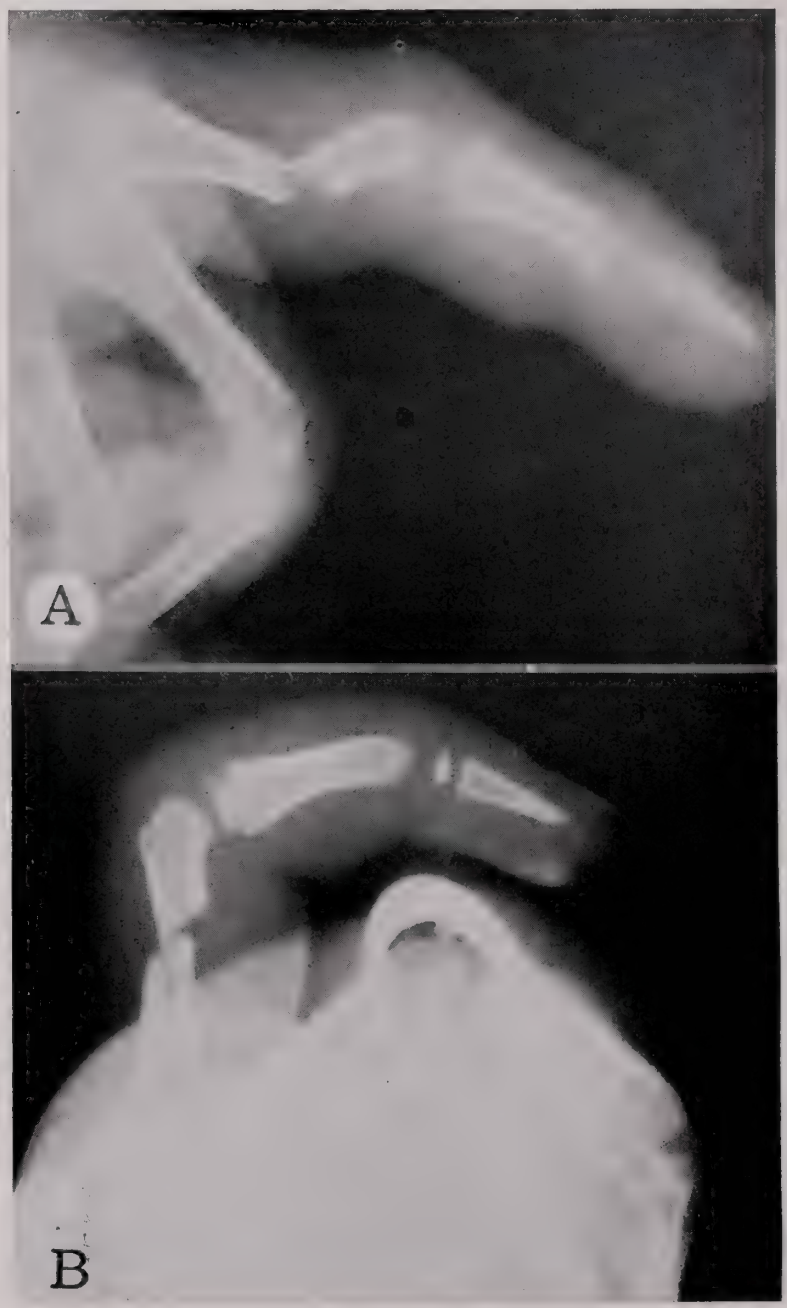

Fig. 3 *(A)*—Fracture of proximal phalanx of right index finger, showing typical deformity. *(B)* Postoperative reduction held by aluminum splint. There is not enough curve of finger and joint to maintain reduction.

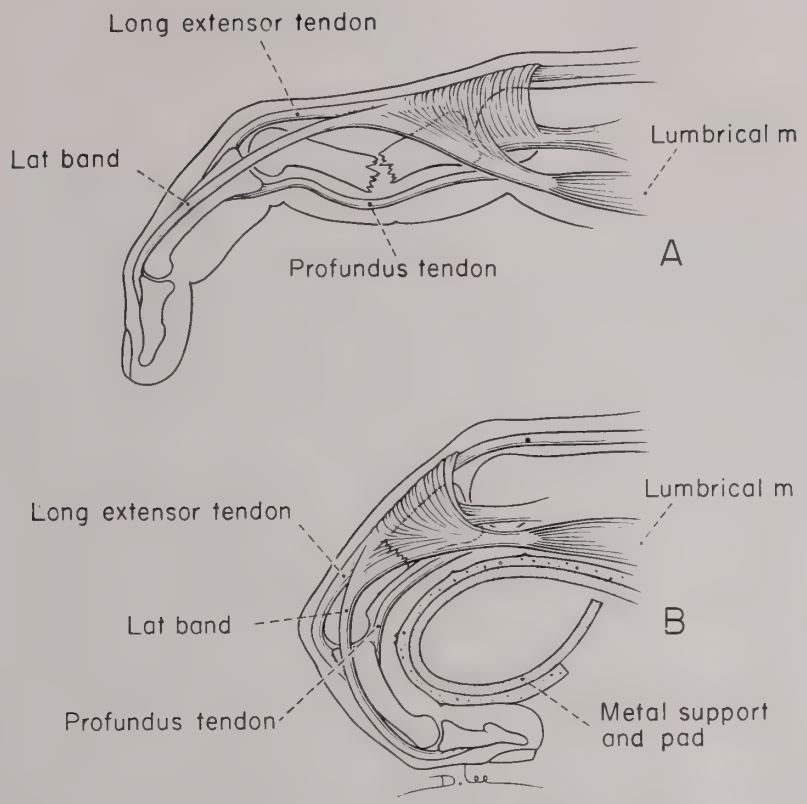

Fig. 4 *(A)*—Demonstration of typical deformity of proximal phalangeal fracture and part played in its production by extensor mechanism. *(B)* Reduction over a splint balances deforming forces.

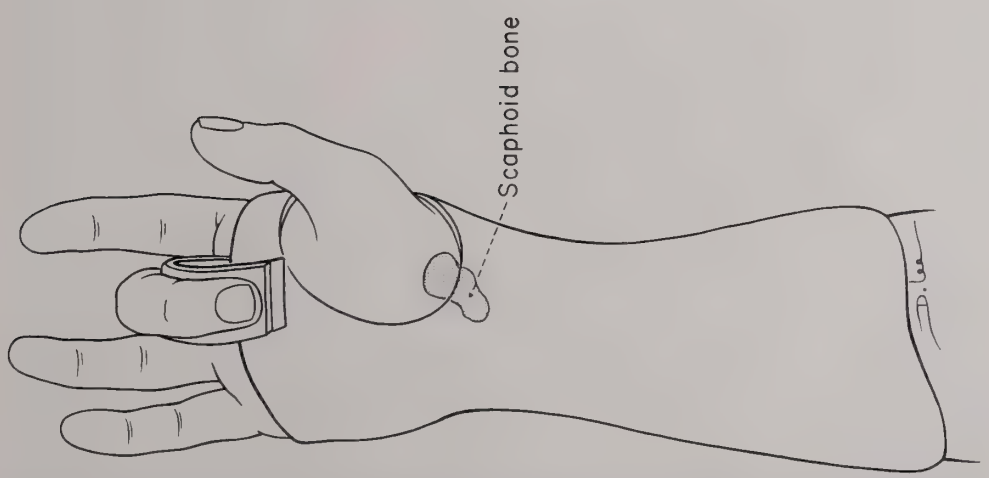

Fig. 5—Demonstration of flexed finger pointing to tubercle of scaphoid on a modified Böhler splint. Normally all fingers point to tubercle of scaphoid when flexed. Nail bed should lie in same plane as adjacent fingers when flexed to control rotation.

fracture of the proximal phalanx. How are you going to treat this?

Dr. Goldman:

Reduce it by manipulation under adequate anesthesia and immobilize it in flexion.

Dr. Linscheid:

Roughly flexion of 40° at the metacarpophalangeal joint, 80° at the proximal interphalangeal joint, and 30° at the distal interphalangeal joint would be usual. The finger would be well curved around a splint device. Do you have to worry about rotation in this fracture, and if so, how would you align it?

Dr. Goldman:

It depends on the type of immobilization used. It is quite difficult with a cast on the fingers. A splint may be twisted to align the finger.

Dr. Linscheid:

Basically you are describing the Böhler type of immobilization. This involves a gauntlet cast with a volar splint on the finger, which is acutely curved. The point to be made here is that one cannot align rotation of the finger unless it is flexed sufficiently to cause the pulp of the finger to face proximally along the forearm. The finger should point toward the tuberosity of the scaphoid (Figure 5). This controls alignment. But to control rotation the nail of the injured finger should lie in the plane of the adjacent fingers. If one tries to control rotation of the finger with the finger only slightly flexed, one has no idea whether or not the finger is going to point toward the scaphoid with full flexion after it has healed. The most common mistake made in the treatment of this type of fracture in the emergency room is not to bend the splint into a tight, closed loop; thus the finger is not held in enough flexion (Figure 4 B). The finger should be pointing in a proximal direction when lying reduced on the splint.

Dr. Paul R. Lipscomb:*

It should be emphasized that this fracture requires anesthesia and manipulation for reduction, before it is put over a splint.

Dr. Linscheid:

A good point. It does take anesthesia by injection into the fracture site or by metacarpal block.

Dr. Richard N. Stauffer:†

Is there any place for pulp traction in this kind of fracture?

Dr. Linscheid:

I haven't found it necessary to use pulp or phalangeal traction; however, it would depend to some extent on how badly the phalanx is fractured and how stable the fracture is. Most of the time, a narrow tape over the fingernail, attaching it to the splint (Figure 5), is sufficient. An alternative is demonstrated in the next case.

Compound Fracture

Dr. Boyce:

A 57-year-old man had a truck jack fall on his right index finger. Exami-

†Resident in Orthopedic Surgery, Mayo Graduate School of Medicine (University of Minnesota), Rochester.

nation at the emergency room disclosed a 5-cm irregular volar laceration and crushing of the skin. The laceration extended into the tendon sheath and exposed the neurovascular bundle (Figures 6 A and B).

Dr. Linscheid:

This represents the same type of injury—essentially a transverse fracture of the proximal phalanx with volar angulation at the fracture site. Here we have a compounding wound with the skin rather abraded, and a laceration that exposes the nerve and vessel. Inspection of the depths of the wound

Fig. 6—*(A)* and *(B)*, Fracture of proximal phalanx of right index finger. *(C)* and *(D)*, Postoperative reduction with crossed Kirschner fixation.

showed that the flexor sheath was stripped off in part, but that the flexor tendons were intact and seemed to be in good condition. How do we treat this wound? Obviously we have to use the same type of wound treatment for a compounding fracture here that we would use in other areas. It must be thoroughly cleaned and debrided of dead or necrotic tissue or any tissue that is irretrievably soiled. We have the added problem of how to maintain the gliding property of these tendons when healing has been completed. This patient was taken to the operating room and the wound was thoroughly cleaned. The neurovascular bundle was protected and the loose fragments of flexor sheath were sharply excised, with exposure of the tendons at the depth of the wound. A tiny pack was inserted into the wound to allow drainage. What happens if we treat this fracture on a Böhler splint and apply pressure under the volar aspect of the finger? We force the flexor tendons against the injured periosteum at the fracture site and increase the chances of having tendinous adhesions. In this situation there is good indication for internal fixation with crossed Kirschner wires (Figures 6 C and D). The finger was easily reduced and the wires were fairly easily inserted percutaneously. The alignment of the finger was checked, the finger being flexed to be sure the pulp was pointing toward the tuberosity. The wound was packed open for 24 hours and then closed with adhesive tape (Steri-strips). Daily motion in the two distal joints to prevent tendinous adhesions was encouraged.

Dr. Lipscomb:

I think I would agree with you. This would be one instance in which one would not want to put the finger in acute flexion and push the structures further in contact with the bone.

Dr. Linscheid:

To summarize, let me make the following points: (1) Rotation as well as alignment of the fragments must be considered in the reduction of phalangeal fractures. (2) If joint surfaces are involved, open reduction and Kirschner wire fixation even in these small finger joints should be considered to effect accurate reduction. (3) The compounding hand injuries still require adequate wound care before the fracture can be treated definitively. (4) Only the injured part should be immobilized, to prevent hand stiffness.

The Progress Notes of Hippocrates

The young man who was lodged by the Liars' Market* was seized with fever from fatigue, labor, and running out of season. On the first day, the bowels disordered, with bilious, thin, and copious dejections; urine thin and blackish; had no sleep; was thirsty. On the second all the symptoms were exacerbated; dejections more copious and unseasonable; he had no sleep; disorder of the intellect; slight sweat. On the third day, restless, thirst, nausea, much tossing about, bewilderment, delirium; extremities livid and cold; softish distention of the hypochondrium on both sides. On the fourth, did not sleep; still worse. On the seventh he died. He was about twenty years of age.†

*Liars' Market—probably a district or neighborhood in Athens.

Diagnostic Possibilities: This might have been an acute heavy metal poisoning; acute parasitic disease; kala-azar, porphyrinuria.

The Physician's Workshop

Side-to-Side Anastomosis of the Small Intestine*

Using Russian Suture Apparatus

A. BLOMER, M.D.*
N. DRAZNIN, M.D.*
U. ROSSECK, M.D.*
Bonn, West Germany

THROUGHOUT THE years a number of surgical suturing machines have been developed. Most of them are based on the stapling principle.

Several instruments designed for thoracic, abdominal and vascular surgery have emanated from the Moscow Institute of Surgical Apparatus and Instruments.[1] Von Petz,[4] in 1924, supplied a method of a reliable, speedy, aseptic, and bloodless closure with his gastrointestinal suturing apparatus.

We evaluated experimentally[2,3] the Russian models† for side-to-side small intestinal anastomoses and an instrument‡ (Figure 1) which is designed for mechanical suturing of the hilum of the lung, and may also be used for bowel closure. Similar to the apparatus of von Petz and Friedrich, a double row of vitallium staples is inserted. After transection of the mesentery the bowel is fixed between the two branches of the clamp by means of a wing nut. A plunger which is activated by pressing on a lateral lever drives first the U-shaped metal clips through the anterior and posterior bowel wall and then bends them into a B-shape.

The apparatus for side-to-side gastroduodenal anastomoses§ (Figure 2) consists of two branches and a plunger with cutting edges. The branches are loaded with two rows of clips which are inserted into the two intestinal lumina through stab wounds and then united. The cutting plunger is then advanced and creates at once a stoma and one-layer anterior and posterior suture lines. The stab wounds are closed with inverting No. 3-O silk sutures.

The Procedure

The operation was performed aseptically under nembutal anesthesia on 12 dogs weighing from 10 to 15 kilograms through an upper mid-line incision. A jejunal loop was isolated by transecting the mesentery for a distance of about 15 cm. Two parallel rows of staples

†UKL-60 and NZKA-60
‡Model UKL-60
§NZKA-60

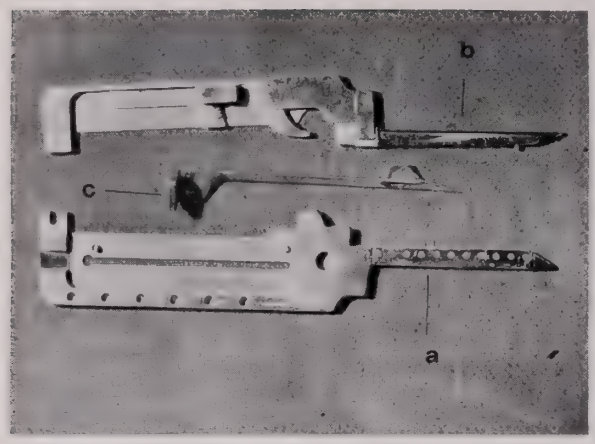

Fig. 1—Apparatus NZKA-60 for side-to-side gastrointestinal anastomoses: (a) Branch with double row of clip compartments. (b) Branch with lay-on surface. (c) Plunger with cutting edge.

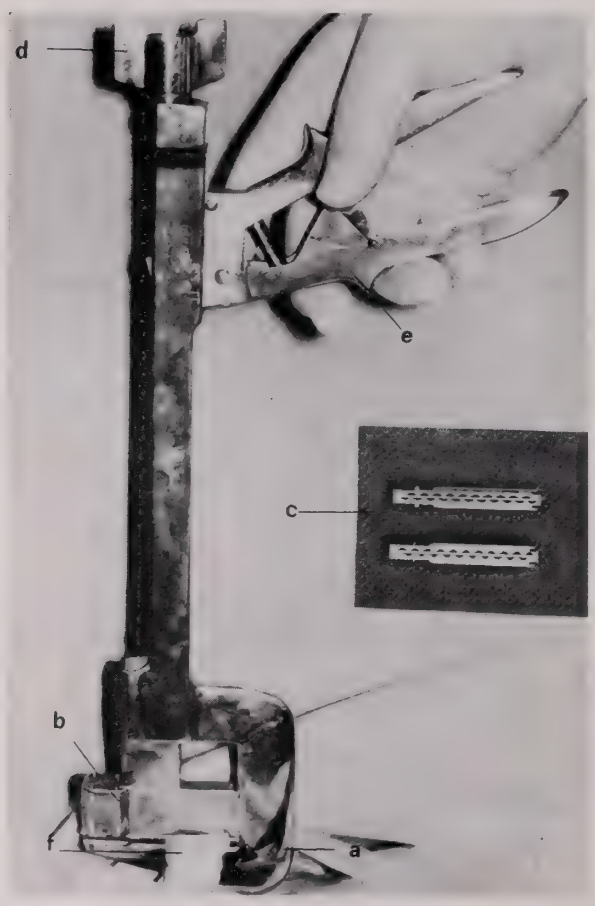

Fig. 2—Apparatus UKL-60 for suturing of pulmonary hilum: (a) Lay-on branch. (b) Clip-branch. (c) Clip container. (d) Nut for apposition of both branches. (e) Activating lever for plunger. (f) Small intestine.

were then applied with the model UKL-60. After excision of the loop both intestinal stumps were additionally inverted with interrupted No. 3 silk sutures. An isoperistaltic anastomosis between the two bowel ends was then done with the model NZKA-60, with simultaneous creation of a stoma. The anterior and posterior rows of clips were additionally secured by rows of seromuscular sutures. On the first two postoperative days the dogs received 500 ml 5.25% glucose and 500 ml of 0.9% normal saline daily. They were fed a semi-liquid diet from the third to the fifth day and solid foods thereafter.

The Observations

The time of sacrifice was varied so as to provide histological examination from the first to the eighth postoperative week. There was one anesthetic death. Eleven dogs survived.

Morbidity

Two dogs had one tarry stool postoperatively. There was no clinical evidence of suture insufficiency in any of the animals. Neither was there radiographic evidence of suture insufficiency of the intestinal stumps in any of the dogs.

Gastrointestinal X-ray examinations with barium were performed under nembutal anesthesia on the sixth postoperative day. There was free passage in all anastomoses. Disturbed bowel motility was found on occasion. However, this was probably due to deep anesthesia rather than a consequence of the operation, since it was present in the entire gastrointestinal tract. Figure 3 showing the open specimen indicates a sufficiently wide anastomosis which can be seen as a fine tissue line.

Microscopic Findings

The microscopic specimens were fixed and imbedded after removal of the metal clips and stained with hematoxylin and eosin and with van Gieson stain. The histological examinations (Figure 4) were of special interest, since they provided a simultaneous comparison of metal clip- and silk-closure. We found remaining silk sutures especially in the submucosa and muscularis propria, surrounded by

chronic granulating, fibrous tissue and foreign body reaction. There were many multinucleated giant cells and larger accumulations of granulocytes resembling abscesses. There was no foreign body reaction in the mucosa. Occasionally we saw a chronic inflammatory infiltration in the mucosa, as it is frequently seen in normal dogs. There was only a mild chronic cicatricial reaction surrounding the empty spaces created by removal of the metal clips.

The Russian suturing apparatus NZKA-60 permits not only the side-to-side small bowel anastomosis but also a side-to-side anastomosis of gastrointestinal tract and colon. We have proved in an earlier experimental series[3] that in using three different Russian suturing apparatuses, a Billroth-I- or Billroth-II-gastrectomy could be done in a reliable way as well as a side-to-side gastroenterostomy and a jejuno-jejunostomy of Braun. The advantages of a mechanical anastomosis are the exact adaptation of the layers and the exact placement of the stoma. Experience and skill on the part of the operating surgeon are not important with this technique.

Fig. 3—Isoperistaltic small intestinal anastomosis, side-to-side, opened, seven weeks postop.

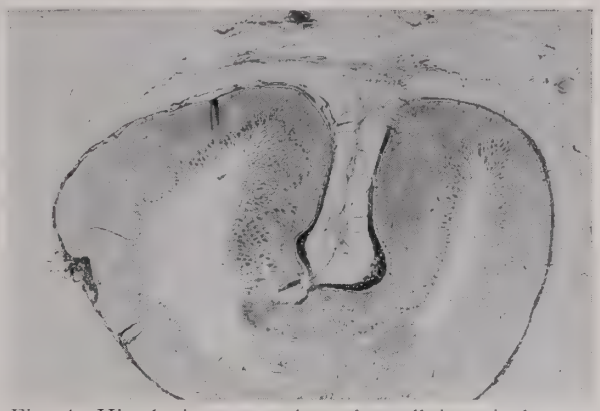

Fig. 4—Histologic preparation of small intestinal anastomosis, six weeks postop.

Summary

Side-to-side small intestinal anastomoses were performed on 12 dogs with the Russian apparatus designed for either gastrointestinal anastomosis or closure of the pulmonary hilum.

The reliability of the mechanical small intestinal anastomosis, as judged by clinical course, X-ray examination and histological findings, was demonstrated.

The Physician's Role

The need for access to the patient and the protective devices which are erected to contain its threat can lead to strains in the doctor-patient relationship. In some ways it is easier for the physician to fill his role if he perceives the patient more as a case than as a person; yet the impersonal approach often runs counter to the emphasis on disease as affecting the whole person and on treating the psyche as well as the soma, and counter to deep psychological needs for love and affection on the part of both the doctor and the patient. This theoretical dilemma has not yet been satisfactorily solved in medical practice.*

*King, S. H. in Richard Magraw: Ferment in Medicine, 1966.

Every new idea has something of the pain and peril of childbirth about it.—Samuel Butler

My Political Creed

I am a free citizen in a free nation.

Whoever diminishes my freedom as an individual diminishes the sum total of freedom in my country.

I am also a physician, free thus far to treat my patients to the best of my ability.

Abridge that freedom and the health of my patients is adversely affected.

These things being true, I cannot--I will not--stand idly by when these hard-won freedoms are under attack.

For I believe that the values upon which this country was founded are immutable and have not been eroded by the passage of years.

I believe that I, as a free citizen in a free land, am obligated to defend my beliefs in the ways permitted to me, and required of me, by our form of government.

Therefore, let no man seek to bar me from the political process; for it would be akin to denying my right to participate in the process that determines free government.

A once-popular treatment for back pains was to have the seventh son of a seventh son stand or walk on the patient's back.

The pain of earache was allegedly relieved by holding a hot roasted onion to the ear.

For headache, a sovereign remedy was to wear a snakeskin round one's head.

A realistic approach to pain relief

BURROUGHS WELLCOME & CO. (U.S.A.) INC.
Tuckahoe, N.Y.

Muscle in Spasm

and Valium (diazepam)

The ability of Valium to help relieve skeletal muscle spasm—as well as psychic tension—demonstrates its clinical value and versatility.

The muscle-relaxant effect obtained with Valium, used adjunctively with other drugs or physiotherapy, favorably affects the entire cluster of spasm-related symptoms . . . helps accelerate return to normal activity.

When skeletal muscle spasm and psychic tension coexist, the calming effect of Valium is an added therapeutic benefit that contributes to the total management of the patient.

Before prescribing, please consult complete product information, a summary of which follows:

Indications: Tension and anxiety states; somatic complaints which are concomitants of emotional factors; psychoneurotic states manifested by tension, anxiety, apprehension, fatigue, depressive symptoms or agitation; acute agitation, tremor, delirium tremens and hallucinosis due to acute alcohol withdrawal; adjunctively in skeletal muscle spasm due to reflex spasm to local pathology, spasticity caused by upper motor neuron disorders, athetosis, stiff-man syndrome, convulsive disorders (not for sole therapy).

Contraindicated: Known hypersensitivity to the drug. Children under 6 months of age. Acute narrow angle glaucoma.

Warnings: Not of value in psychotic patients. Caution against hazardous occupations requiring complete mental alertness. When used adjunctively in convulsive disorders, possibility of increase in frequency and/or severity of grand mal seizures may require increased dosage of standard anticonvulsant medication; abrupt withdrawal may be associated with temporary increase in frequency and/or severity of seizures. Advise against simultaneous ingestion of alcohol and other CNS depressants. Withdrawal symptoms have occurred following abrupt discontinuance. Keep addiction-prone individuals under careful surveillance because of their predisposition to habituation and dependence. In pregnancy, lactation or women of childbearing age, weigh potential benefit against possible hazard.

Precautions: If combined with other psychotropics or anticonvulsants, consider carefully pharmacology of agents employed. Usual precautions indicated in patients severely depressed, or with latent depression, or with suicidal tendencies. Observe usual precautions in impaired renal or hepatic function. Limit dosage to smallest effective amount in elderly and debilitated to preclude ataxia or oversedation.

Side Effects: Drowsiness, confusion, diplopia, hypotension, changes in libido, nausea, fatigue, depression, dysarthria, jaundice, skin rash, ataxia, constipation, headache, incontinence, changes in salivation, slurred speech, tremor, vertigo, urinary retention, blurred vision. Paradoxical reactions such as acute hyperexcited states, anxiety, hallucinations, increased muscle spasticity, insomnia, rage, sleep disturbances, stimulation, have been reported; should these occur, discontinue drug. Isolated reports of neutropenia, jaundice; periodic blood counts and liver function tests advisable during long-term therapy.

Valium®(diazepam)
2-mg, 5-mg, 10-mg tablets

ROCHE
Roche® LABORATORIES
Division of Hoffmann-La Roche Inc.
Nutley, New Jersey 07110

A little

Just one 50 or 100 mg tablet in the morning can work a long diuretic day in edema and hypertension.

HY-6060

Hygroton® can work a long day too

hlorthalidone

hat's because of its prolonged ıction, which usually provides mooth diuretic activity hroughout the day. And ne-a-day dosage means few ablets to take and few tablets o pay for in the long run.

Hygroton, brand of chlorthalidone, may mean troublesome side effects for certain patients. And you can't prescribe it in cases of demonstrated hypersensitivity to the drug or in severe renal or hepatic diseases.

Before writing it for your patients, please check the Prescribing Information. It's summarized on the next page.

Hygroton

hlorthalidone in edema and hypertension

Geigy

in edema and hypertension

A little Hygroton® can work a long day

chlorthalidone

Indications: Hypertension and many types of edema involving retention of salt and water.

Contraindications: Hypersensitivity and most cases of severe renal or hepatic diseases.

Warning: With the administration of enteric-coated potassium supplements, which should be used only when adequate dietary supplementation is not practical, the possibility of small-bowel lesions (obstruction, hemorrhage, and perforation) should be kept in mind. Surgery for these lesions has been required frequently and deaths have occurred. Discontinue enteric-coated potassium supplements immediately if abdominal pain, distention, nausea, vomiting, or gastrointestinal bleeding occur.

Use with caution in pregnant women and nursing mothers since the drug may cross the placental barrier and appear in cord blood and since thiazides may appear in breast milk. The drug may result in fetal or neonatal jaundice, thrombocytopenia, and possibly other adverse reactions which have occurred in the adult. When used in women of childbearing age, balance benefits of drug against possible hazards to fetus.

Precautions: Antihypertensive therapy with this drug should always be initiated cautiously in postsympathectomy patients and in patients receiving ganglionic blocking agents, other potent antihypertensive drugs or curare. Reduce dosage of concomitant antihypertensive agents by at least one-half. Because of the possibility of progression of renal damage, periodic determination of the BUN is indicated. Discontinue if the BUN rises or liver dysfunction is aggravated. Hepatic coma may be precipitated.

Electrolyte imbalance, sodium and/or potassium depletion may occur. If potassium depletion should occur during therapy, the drug should be discontinued and potassium supplements given, provided the patient does not have marked oliguria.

Take special care in cirrhosis or severe ischemic heart disease and in patients receiving corticosteroids, ACTH, or digitalis. Salt restriction is not recommended.

Adverse Reactions: Nausea, gastric irritation, vomiting, anorexia, constipation and cramping, dizziness, weakness, restlessness, hyperglycemia, glycosuria, hyperuricemia, headache, muscle cramps, orthostatic hypotension, which may be potentiated when chlorthalidone is combined with barbiturates, narcotics or alcohol, aplastic anemia, leukopenia, thrombocytopenia, agranulocytosis, impotence, dysuria, transient myopia, skin rashes, urticaria, purpura, necrotizing angiitis, acute gout, and pancreatitis when epigastric pain or unexplained G.I. symptoms develop after prolonged administration. Other reactions reported with this class of compounds include: jaundice, xanthopsia, paresthesia, and photosensitization.

Average Dosage: 50 or 100 mg. with breakfast daily or 100 mg. every other day.

Availability: White, single-scored tablets of 100 mg. and aqua tablets of 50 mg., in bottles of 100 and 1000.

Clinical Path Conference

Coarctation of Aorta as Part of Shone Syndrome*

Dr. George R. Noren:†

A male infant was born to a 20-year-old primagravida with no history of prenatal complications. The one-minute Apgar was three; at 10 minutes it was 10. Initial physical examination revealed no abnormalities. The weight of the infant was 2900 grams. On the second day of life, a grade II/VI ejection systolic murmur was heard along the left lower sternal border and the femoral pulses were thought to be weak. The pulmonary second sound was greatly accentuated. Simultaneous blood pressures were then done. The left and right arms flushed at 120 mm. Hg. and the legs at 40 mm. Hg. No cyanosis was noted. An electrocardiogram obtained at that time revealed right ventricular hypertrophy. Thoracic roentgenograms demonstrated questionable right basilar pneumonia. The overall cardiovascular silhouette was within normal limits. The infant fed slowly but gained weight consistently. He did not demonstrate any evidence of cardiac failure and was discharged at two and a half weeks of age.

The infant was admitted for the second time when three months old. The history was that for two weeks there had been slow feeding and inadequate gain in weight. Physical examination revealed abnormalities of the cardiovascular system. The point of maximum cardiac impulse was felt at the anterior axillary line in the fourth left intercostal space. A grade III/VI systolic ejection murmur was present. It was loudest along the left sternal border and radiated to the left axilla and left shoulder and posteriorly along the spine. The second cardiac sound in the pulmonary area was accentuated. The edge of the liver was palpated 2 cm. below the right costal margin. The femoral pulses were faintly palpable bilaterally and there were bounding brachial and carotid pulses. By the flush method the

*This study was supported by Public Health Service Research Grant 5 RO1 HE05694 and Research Training Grant 2 T1 HE05570 from the National Heart Institute.

†Associate Professor, Department of Pediatrics, University of Minnesota, Minneapolis; Assistant Chief, Department of Pediatrics, Hennepin County General Hospital, Minneapolis.

blood pressure in the right arm was 125 mm. Hg. and in the leg, 80 mm. Hg. The electrocardiogram demonstrated severe right ventricular hypertrophy, as in the first admission.

Over the next several days it was decided that borderline congestive heart failure was present and the patient was digitalized on the basis of 0.07~~0.7~~ mg. Lanoxin per kilogram of body weight. Following digitalization the condition of the infant improved and he was discharged one week after the second admission.

The infant was then followed in the Pediatric Cardiology Clinic and gained weight very slowly. At age six months, the blood pressure in the arms was noted to be 150 mm. Hg., respirations 90 per minute and pulse 150 per minute. The weight at that time was 12 pounds. There was a grade III/VI loud systolic ejection murmur heard best along the left sternal border. The murmur radiated well to the left axilla and back. There was a loud pulmonic second sound with questionable splitting. The liver was palpated 3 to 4 cm. below the right costal margin. An electrocardiogram revealed an axis of 85 degrees with probable left atrial enlargement. Signs of severe right ventricular hypertrophy and probable left ventricular hypertrophy were apparent. A thoracic roentgenogram showed left ventricular predominance and pulmonary vascular congestion.

A retrograde aortogram was then performed from the right brachial artery and the patient was transferred to the surgical department because of increasing cardiac decompensation.

Following an operation which was uneventful the respiratory rate was 62 per minute with retractions and expiratory grunting. The respiratory rate continued to increase with evidence of increasing congestive heart failure. Moist rales were heard over both lung fields. Immediately after operation, the blood pressure in an arm was 130 mm. Hg. and in the legs, 130 mm. Hg. The levels of electrolytes in the blood were all within normal limits with the exception that, postoperatively, the level for SGOT was 250 units. Despite intensive medical measures, the infant's course deteriorated and death occurred 24 hours after operation.

Dr. Gary E. Gathman:*

This six-month-old infant was born to a 20-year-old primagravida after an uncomplicated pregnancy. His birth weight was 2900 grams, which would indicate that he was probably a term infant, although his weight is near the lower limits of normal. Prematurity both by birth weight and gestational age, is approximately two and a half times more frequent in children with congenital heart disease than in those with normal hearts.

The patient was a male, which statistically would increase his chances of having aortic stenosis, tetralogy of Fallot, transposition of the great vessels, and/or coarctation of the aorta. Various authors have reported that the incidence of coarctation is two to four times greater in males than in females. He was quite depressed one minute after birth, which could significantly increase his perinatal mortality; however, the situation improved and at ten minutes his Apgar score was 10. The initial physical examination was normal, but one must wonder whether or not accurate evaluation of the femoral pulses was made.

On the second day of life a grade II/VI ejection systolic murmur was

*Assistant Professor, Department of Pediatrics, University of Minnesota, Minneapolis.

heard along the left lower sternal border and the femoral pulses were felt to be weak. Simultaneous blood pressures were then obtained; the left and right arms flushed at 120 mm., the legs at 40 mm. No cyanosis was present then, and apparently none was present at any time until shortly before his demise. An electrocardiogram revealed right axis deviation, a suggestion of right atrial hypertrophy, and rather marked right ventricular hypertrophy (Figure 1). A thoracic roentgenogram demonstrated a normal-sized heart with questionable basilar pneumonia. At this time the clinical and laboratory findings are quite consistent with a diagnosis of coarctation of the aorta. With the absence of differential cyanosis and equal blood pressures in both arms, the coarctation is distal to the ligamentum arteriosum. Neither subclavian artery is stenotic nor does either rise below the level of coarctation. The absence of cyanosis rules out aortic atresia or interruption of the aortic arch with the distal aortic supply coming from a patent ductus arteriosus.

Conservative medical management was adopted as the treatment of choice. The infant fed slowly but gained weight consistently and did not demonstrate any evidence of congestive heart failure. Coarctation of the aorta is the most frequent cause of congestive heart failure in the first week of life. He was discharged at two and a half weeks of age but was readmitted at three months of age because of a two-week history of slow feeding and poor gain in weight. This history is unusual for a simple severe coarctation in infancy. Generally, these infants are in trouble before three months of age.

Physical examination at this time was unremarkable except for the heart

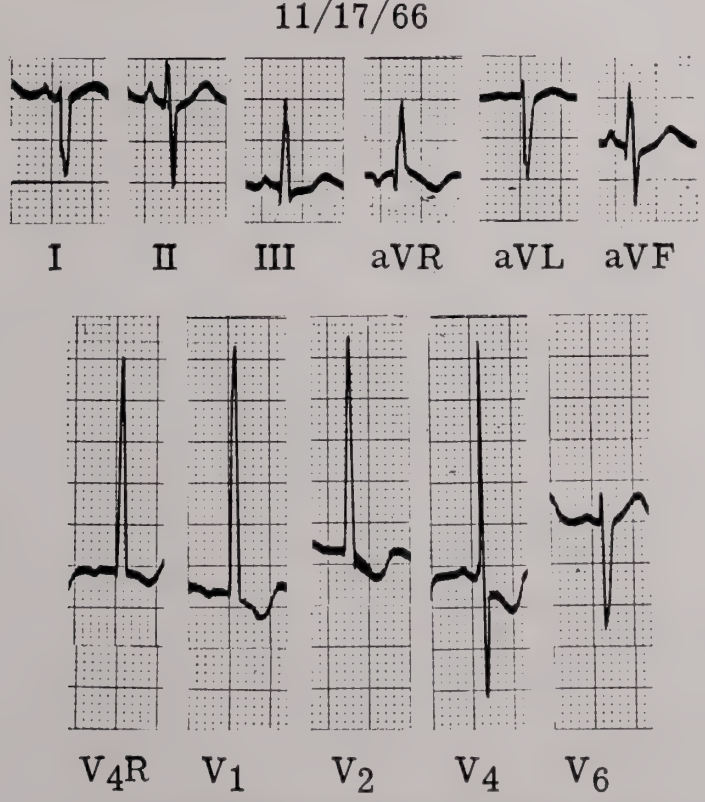

Fig. 1—Electrocardiogram made in the newborn period.

which was enlarged to the anterior axillary line in the fourth intercostal space. A grade III/VI ejection systolic murmur was heard loudest along the left sternal border with radiation to the axilla and left shoulder and along the spine posteriorly. The second heart sound, and presumably this was the pulmonic component of the second heart sound, was again accentuated. The liver was palpated 2 cm. below the right costal margin. The femoral pulses were faint and there were bounding brachial and carotid pulses. Blood pressure by flush method in the right arm was 120 mm. and 80 mm. in the legs. Because of clinical suggestion of borderline congestive heart failure, the patient was digitalized with an adequate dose of Lanoxin (0.07 mgm. per kgm.). He improved and was discharged. Delicate medical management was then continued as the treatment of choice for an infant with coarctation.

At six months of age the child was clearly in trouble again with tachycardia, tachypnea, and hypertension. His weight had leveled off to well below the third percentile for his age. Again a grade III/VI loud systolic murmur was heard along the left sternal border radiating well to the axilla and back with a loud pulmonic second sound but again with questionable splitting. The liver was palpated 3 to 4 cm. below the right costal margin. The electrocardiogram at six months of age is markedly abnormal (Figure 2). There is severe right ventricular hypertrophy with a QRS axis of about 90 degrees. This axis is further to the left than one might expect in a child with this degree of right ventricular hypertrophy. The P and T wave axes are about 60 degrees. The T waves are not diagnostic of strain, although there is some slight ST segment depression probably secondary to digitalis. The PR interval of .12 sec. is normal for this age and heart

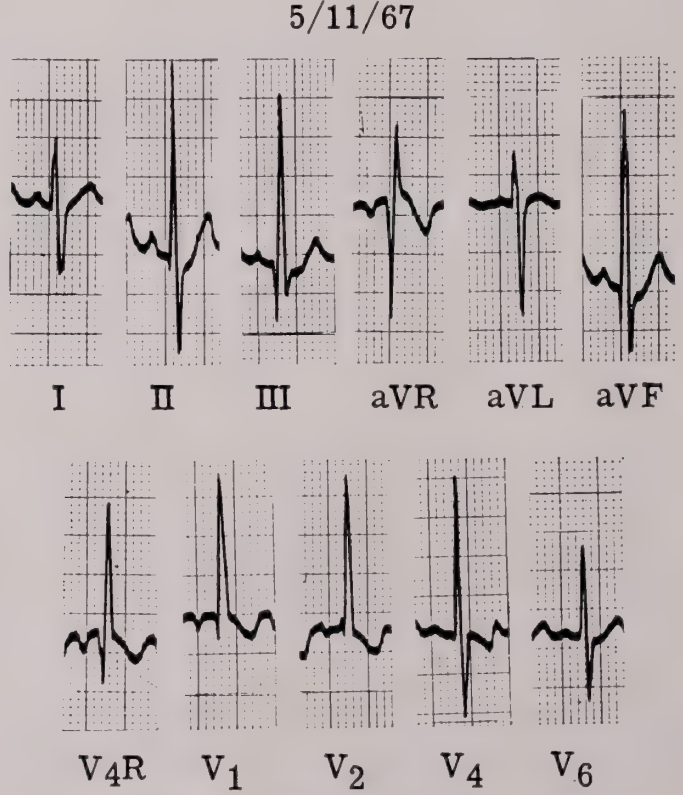

Fig. 2—Electrocardiogram made at the age of six months.

rate. The QT interval of .28 sec. with a QT_c of .45 sec. is abnormally long and is suggestive of strain. The QRS interval of 0.08 sec. is somewhat prolonged and suggests a right ventricular conduction delay, quite possibly on the basis of right ventricular hypertrophy. There are deep T waves in Leads III and aVF associated with tall R waves in Lead aVF, features which point to left ventricular hypertrophy, in addition to the severe right ventricular hypertrophy. The R wave in Lead V_6 is 24 mm., again supporting evidence of left ventricular hypertrophy. The T waves in Lead V_6 are upright and do not suggest left ventricular strain. The P wave in Lead III is 3 mm., suggesting right atrial hypertrophy. While there is no broad notching of the P waves reflecting left atrial potentials, there is inversion of the P wave in Lead V_4R and V_1, and a diphasic P wave in Lead V_2. These changes suggest additional left atrial hypertrophy. The electrocardiogram, therefore, shows severe right ventricular hypertrophy with associated left ventricular hypertrophy. In addition, there is right atrial hypertrophy and probably left atrial hypertrophy. This electrocardiogram is not consistent with severe coarctation at six months of age, because generally by this time the right ventricular hypertrophy has decreased and, more significantly, left ventricular hypertrophy has appeared. The electrocardiogram does help in ruling out glycogen storage disease of the heart because of the normal PR interval and the absence of the equiphasic voltages in the precordial leads. A severe electrolyte disturbance is also ruled out and, while we cannot be absolutely certain that endocardial fibroelastosis is not present, the normal T wave axis and the upright T waves in Lead V_6 are evidence against this diagnosis. The protocol tells us that a thoracic roentgenogram showed left ventricular predominance with pulmonary vascular congestion at six months of age. May we see the films at this time?

Dr. S. H. Tsai:*

The chest film at the time of birth was within normal limits. The next film (Figure 3a) was taken at three months of age and shows definite car-

*Assistant Professor, Department of Radiology, University of Minnesota, Minneapolis; Chief, Department of Radiology, Hennepin County General Hospital, Minneapolis.

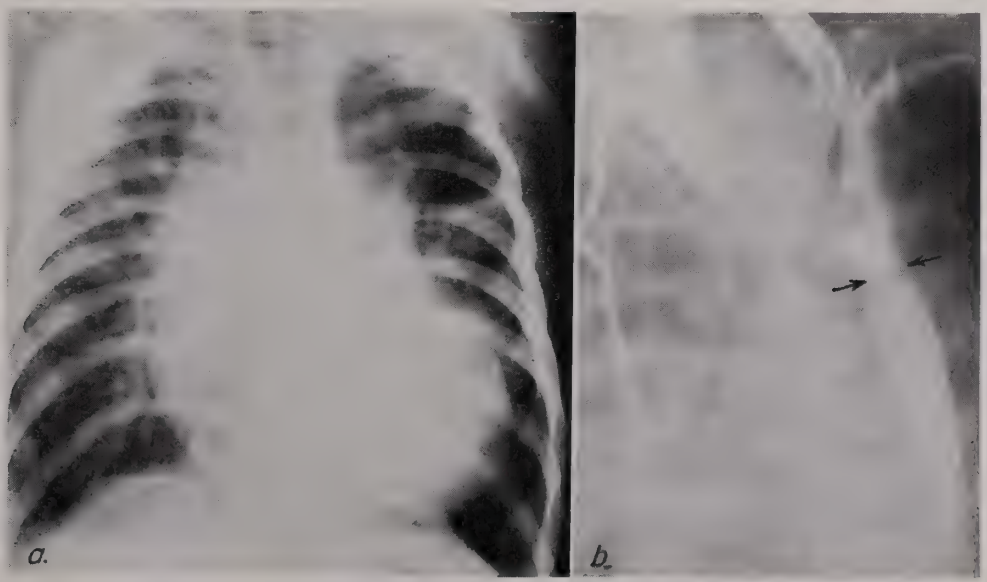

Fig. 3—(a) Frontal view of thoracic roentgenogram. (b) Aortogram, coarctation of aorta (between arrows).

diac enlargement and pulmonary vascular congestion which is more likely a result of venous congestion rather than increased blood flow. This film shows enlargement of the left atrium and also of the left ventricle. There is no positive evidence for right ventricular enlargement. Studies at six months of age continued to show cardiomegaly and pulmonary congestion.

Dr. Gathman:

A retrograde aortogram was then performed from the right brachial artery. This undoubtedly confirmed the presence of coarctation of the aorta which was clinically diagnosed on the second day of life. May we see the aortogram?

Dr. Tsai:

A retrograde aortogram was performed from the right brachial artery (Figure 3b). This confirmed the clinical impression of coarctation of the aorta which seemed clinically apparent on the second day of life. The ascending aorta did not become opacified in any of the films.

Dr. Gathman:

Because of increasing decompensation, the infant was sent to surgery, which was uneventful and presumably resulted in a good repair of the coarctation, with equal blood pressures in the arms and legs postoperatively. A systolic blood pressure of 130 mm. in the postoperative period is not very unusual, even in an infant, and would help me to rule out associated renal artery stenosis. Postoperatively he deteriorated with evidence of increasing congestive heart failure and the development of moist rales over both lung fields. Other than the chest film, this is the first definite evidence we have of left-sided congestive heart failure. The patient was not in electrolyte imbalance and, despite intensive medical management, he expired 24 hours postoperatively.

We now have the difficult task of synthesizing the information given to us in the protocol in order to explain why this child died postoperatively. One of the frequent defects occurring with coarctation of the aorta, patent ductus arteriosus, has been ruled out by the aortogram. Transposition of the great vessels has also been ruled out by the absence of cyanosis and the normal position of the aorta. Glycogen storage disease has been ruled out by the electrocardiogram. Endocardial fibroelastosis is also unlikely.

What then caused the severe pulmonary hypertension present in this patient? It could have been an associated ventricular septal defect; however, usually coarctation repair results in clinical improvement by decreasing left ventricular pressure. It would also be unusual for a patient with coarctation and a ventricular septal defect to have biventricular hypertrophy; pure right ventricular hypertrophy is more frequent. Pulmonary venous congestion is also not usually present. An associated atrial septal defect should again have been helped by coarctation repair. We must, therefore, direct our attention to associated defects of the left side of the heart, and in this patient the chest film beginning at three months of age showed predominantly left-sided congestive heart failure.

Cor triatriatum is a possibility; but left atrial hypertrophy on the electrocardiogram, even in the presence of coarctation, would tend to argue against this diagnosis. Abnormalities of the mitral valve may be present with coarctation; however, no diastolic murmur has been mentioned and, while

this need not be present with congenital mitral stenosis or parachute mitral valve, I would have expected this patient to have been in trouble sooner from a clinical standpoint. Congenital or acquired mitral insufficiency associated with endocardial fibroelastosis or infarction of the papillary muscles is unlikely because of the absence of significant ST-T wave changes. Therefore, it seems unlikely to me that this patient had hemodynamically significant mitral valvular disease.

Although we are not told so by the protocol, I feel that this patient was left with a systolic ejection murmur after the coarctation was repaired. Abnormalities of the aortic valve ranging from a bicuspid valve to aortic atresia have been reported in as many as 85 percent of cases with coarctation of the aorta and I would anticipate that this patient had a bicuspid aortic valve. I was hoping that the aortogram would rule out supravalvular aortic obstruction; however, it did not. There is no mention in the protocol of any abnormal facies or evidence of idiopathic hypercalcemia, and I think this helps in ruling out the hypercalcemia syndrome. It would also be extremely unusual for a patient with idiopathic hypercalcemia and supravalvular aortic stenosis to develop symptoms of severe congestive heart failure at this young age.

I have not yet explained his down-hill course after the repair of the coarctation, but I doubt that a significant degree of aortic valvular stenosis was present, on statistical grounds alone. In a recent publication Rowe and Mehrizi[1] describe a syndrome of coarctation of the aorta, subaortic stenosis, and other left-sided lesions as being differentiated by a murmur low along the left sternal border, a split-second sound with a markedly accentuated pulmonic component, and an enlarged heart with increased pulmonary vascularity. I would, therefore, like to conclude that the hemodynamically significant lesions in this child were: (1) coarctation of the aorta and (2) subvalvular aortic stenosis. I think the clues that would have helped me to make this diagnosis antemortem were the extremely loud pulmonic second sound and the evidence of severe pulmonary hypertension persisting at six months of age. I feel the loud systolic murmur heard best at the left sternal border is also significant.

In the terms of the clinical management of this patient, it would appear that he was handled very well. My only suggestion that might have helped to further evaluate his problem would be a left ventriculogram at the time of the aortogram.

Clinical Diagnoses:

1. Coarctation of the aorta.
2. Congenital subaortic stenosis.

Dr. Jesse E. Edwards:*

The essential findings at necropsy were found in the thorax, particularly in the heart and great vessels (Figures 4 and 5). There was evidence of resection of coarctation of the aorta with an end-to-end anastomosis, resulting in a lumen almost as wide as the aorta proximal and distal to the site of coarctation. Cardiomegaly was a feature in which the heart was somewhat more than twice normal weight. The major reason for the cardiac enlargement was hypertrophy of the myocardium of each ventricle.

---

*Director of Laboratories, The Charles T. Miller Hospital, St. Paul; Clinical Professor of Pathology, School of Medicine and Professor of Pathology, Graduate School, University of Minnesota, Minneapolis; and Consultant, Hennepin County General Hospital, Minneapolis.

In the outflow tract of the left ventricle beneath a congenital bicuspid aortic valve the hypertrophied muscle protruded somewhat toward the left ventricular cavity, suggesting an element of hypertrophic muscular subaortic stenosis. In the left ventricle the arrangement of the papillary muscles was abnormal. This was characterized by the fact that, although two muscles were present, these were closely aligned and inserting into the lateral wall of the left ventricle. No papillary muscles were present at the junction of the posterior and septal walls. The mitral valve possessed two leaflets and the chordae inserted into the closely aligned papillary muscles. The appearance of the papillary muscles approached that seen in the parachute mitral valve, although the convergence of the chordae toward a single papillary muscle was not as striking as in classic examples of the parachute mitral valve, since two papillary muscles were present. Attached to the basal aspect of the atrial surfaces of the mitral leaflets was a low ridge of fibrous tissue which protruded into the lumen at the inlet to the mitral valve. Although this condition bears the name supravalvular ring of the left atrium and, although in some instances this lesion may cause severe obstruction to egress of blood from the left atrium, in this case it did not seem to be a significant feature in view of the minimal extent of this lesion. The left atrial chamber was dilated, the wall was hypertrophied, and the endocardium was distinctly thickened.

A ventricular septal defect was observed beneath the aortic valve, the defect centering beneath the right aortic cusp. Instead of leading into the right ventricle this defect led through a cleft in the tricuspid valve and to the right atrium, the aggregate representing a left ventricular-right atrial canal. Pouch-like structures were attached to the tricuspid valve, the de-

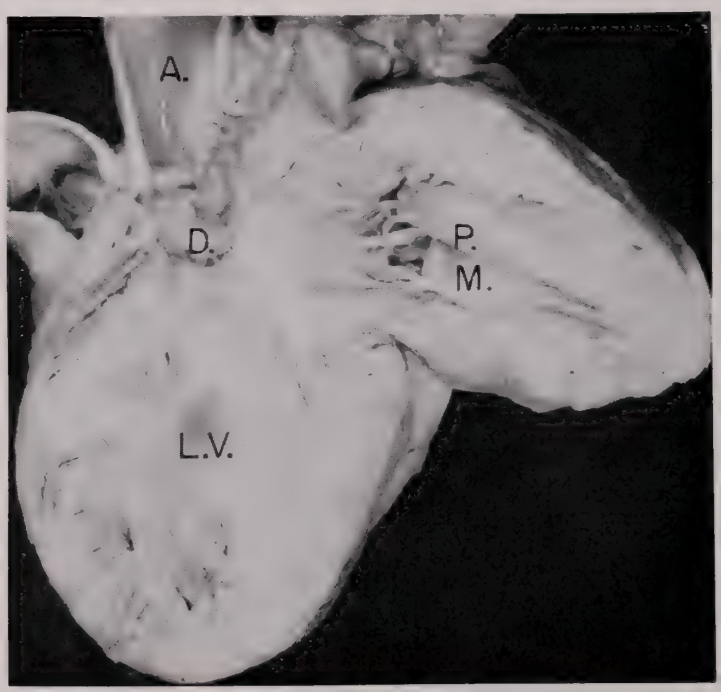

Fig. 4—Left ventrical (L.V.) and ascending aorta (A). Major hypertrophy of the left ventricular wall with prominence in the subaortic area. Defect (D.) is present in the ventricular septum and leads to a left ventricular-right atrial communication. The two papillary muscles (P.M.) lie closely aligned and insert into the lateral wall of the left ventricle.

tails of which were reported by Chesler and associates.[2] The right ventricular wall was hypertrophied and, in the outflow portion, the stout muscle bundles encroached upon the lumen, suggesting the presence of an element of right ventricular outflow obstruction. In essence, in this case there is a phenomenon of major muscular hypertrophy with a prominence in the subaortic area that may have caused subaortic stenosis and prominence in the subpulmonary area which may have been associated with some infundibular stenosis, although we do not have the catheterization data to prove these points. The muscular hypertrophy may represent idiopathic myocardial hypertrophy, for want of a better name.

As we discuss this case in relation to the pathologic findings as they relate to the clinical features, there was a coarctation of the aorta; but after the coarctation was corrected, there was still a problem of pulmonary venous obstruction. There was an element of a left-to-right shunt through the left ventricular-right atrial communication which, of itself, may not have been of major significance. What seems to have been important is the major hypertrophy of the left ventricle which probably caused a barrier to the free flow into the left ventricle; in this way, the muscular hypertrophy would constitute a situation very similar to that in mitral stenosis. There may also be an element of inflow obstruction into the right ventricle on the basis of the major hypertrophy of the right ventricle and in each ventricle, in addition, an element of outflow obstruction. In this case, the presence of coarctation of the aorta, supravalvular ring of minor degree, a deformity of the mitral valve in the direction of a parachute mitral valve, and the presence of subaortic stenosis call to mind a syndrome recognized here in the Twin Cities several years ago. Finally reported by Shone and others, we call it the Shone syndrome.[3] It has four obstructive anomalies in the left side of the heart: supravalvular ring of the left atrium,

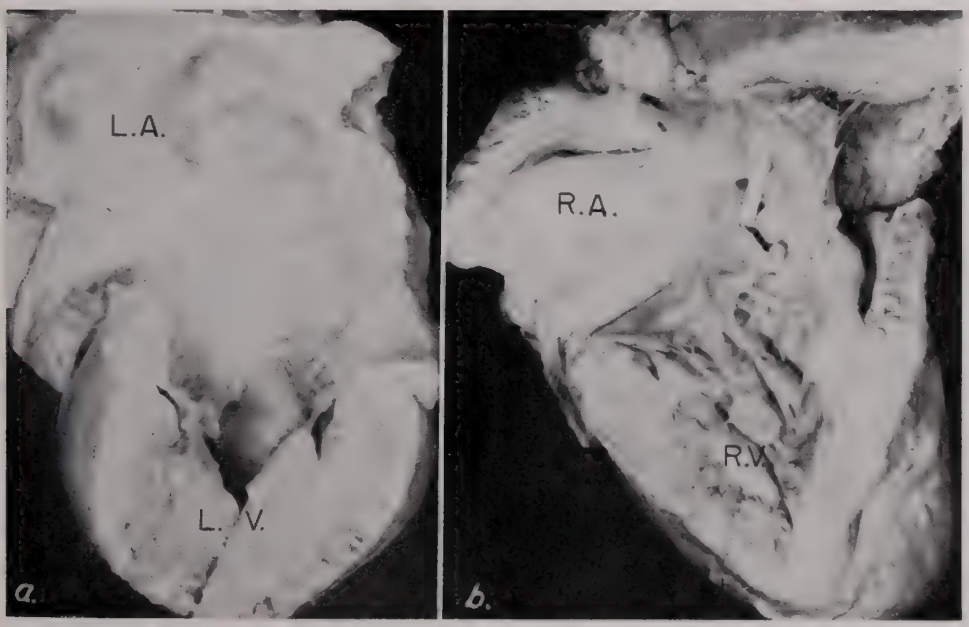

Fig. 5—(a) Left atrium (L.A.) and left ventricle (L.V.). The left ventricular myocardium shows major hypertrophy. The left atrial chamber is enlarged, its endocardium thickened and its myocardium hypertrophied. (b) Right atrium (R.A.) and right ventricle (R.V.). A cleft in the tricuspid valve allows a left ventricular-right atrial communication (probe). Major hypertrophy of the right ventricular wall associated with suggestion of infundibular stenosis.

parachute mitral valve, subaortic stenosis, and coarctation of the aorta.

I think this case illustrates the Shone syndrome. In the normal mitral valve, the two papillary muscles are quite a distance from each other and the chordae of the mitral valve diverge to insert into the two papillary muscles. In the classical parachute mitral valve there is one group of papillary muscles and, while there are two mitral leaflets, the chordae converge to insert into the single papillary muscle. Such a valve may be stenotic if the spaces between the chordae are small, as occurs in some cases. In the current case, I do not believe that the mitral anomaly contributed to mitral stenosis. A supravalvular ring was also present but was of minor proportion.

Among the eight cases that Shone reported, there was variation in how severe each lesion was and also in how many of the four elements of the syndrome were present in any one case. In one case, there was the complete picture from the point of view of the anatomic lesions and the functional significance of each. In some other cases all four lesions were present, but in none was each lesion functionally significant. In the case presented, I would say the supravalvular ring and the mitral deformity were not significant, the subaortic stenosis was of questionable significance, and the coarctation was obstructive. The diffuse myocardial hypertrophy was probably the significant factor in causing pulmonary venous obstruction. It is of interest that the left ventricular-right atrial communication present in the case today is not the first seen in conjunction with the Shone syndrome. In Shone's series there was a 13-year-old child with a left ventricular-right atrial communication which was closed at operation. In the case presented, the shunt through the left ventricular-right atrial communication would serve to compound the effects of the hypertrophied left ventricle in causing pulmonary venous obstruction.

Also, a fairly heavy thread of bicuspid aortic valve runs through the cases. It is interesting that in one of Shone's cases without coarctation, a bicuspid aortic valve was present. We may close this discussion by making the generalization that coarctation of the aorta may be a serious condition in infancy and its presence may mask the presence of additional conditions. Another axiom is that if a coarctation is properly repaired and the patient continues to have symptoms, there is some additional condition present. Some of you who read the old literature might say that is just as we expected because the old idea was that, in the presence of a symptomatic infant with coarctation, there most certainly would be another condition. We know that this is not true, because there are patients who have coarctation as the only significant abnormality. Yet others have other conditions. Therefore, one does have to exercise an awareness of the possibility of other conditions present in the symptomatic infant with coarctation. It is convenient to know about the Shone syndrome, since among some of the patients with coarctation who have continued trouble after the coarctation is resected, one or another element of the four lesions of the Shone syndrome may contribute to the trouble.

Diagnoses:

1. Coarctation of aorta.
2. Idiopathic cardiac hypertrophy with muscular subaortic and subpulmonary stenosis.
3. Supravalvular ring of left atrium.
4. Parachute mitral valve.

5. Left ventricular-right atrial communication.
6. Bicuspid aortic valve.
7. Pouches of tricuspid valve.

His Nganga* Failed

Francis:† a MuZezuru from Enkeldoorn, aged thirty. He suffered from epilepsy and had his first fit in 1950 and since then had had an attack every three years. A year before coming to hospital, he had consulted a diviner who told him that the spirit of his late wife was annoyed with him for refusing to marry her sister; it was so annoyed that it was operating as an angered spirit—a ngozi. First it troubled her own parents and they consulted a nganga who diverted it back to Francis; it was then that his epilepsy started. In 1959 he married his sister-in-law but he still suffered from fits, so he sought advice from a nganga who suggested that he chase the ngozi back to his father-in-law, and gave him herbal remedies for the fits. Francis took the medicine, but up to the time he came into the hospital he had not arranged with the nganga to drive the ngozi to his father-in-law.‡

*Nganga—Southern Rhodesian witch doctor.

†Francis was admitted to a Southern Rhodesian hospital after his nganga failed to cure him.

Disease as Reprisal III

Why was Gehazi smitten with leprosy?

Under false pretenses he had requested and received from Naaman a gift of money and clothing, a sin he subsequently failed to confess to his master, Elisha, who then proclaimed:

The leprosy therefore of Naaman shall cleave unto thee, and unto thy seed for ever. And he went out from his presence a leper white as snow. (II Kings 5:27)

To forgive and forget means to throw valuable experience out the window.
—Schopenhauer

New drugs take exams, too.

Today, virtually every medical school in the United States cooperates with pharmaceutical manufacturers in the clinical evaluation of new and promising drugs. Just as you might find it significantly more difficult to practice medicine without the useful new compounds made available through original pharmaceutical research in the past twenty years—prescription-drug manufacturers would find it equally difficult to obtain extensive, long-term, dependable evaluations of new therapeutic agents without the close cooperation of medical staffs and clinical facilities of medical schools and teaching hospitals. Such cooperation leads toward more effective care of more patients—the common goal of medical and pharmaceutical research—toward reduction in the cost of disease, toward increase in useful longevity.

This message is brought to you as a courtesy of this publication on behalf of the producers of prescription drugs.

Neurotoxicity of Antibiotics

THE USE OF antibiotics is occasionally compromised by various neurotoxic reactions that involve the peripheral nervous system as well as the central nervous system.

The mechanisms of antibiotic action are incompletely understood. The substances, produced by living organisms, inhibit the growth and activity of other living organisms.[1] To be clinically useful, antibiotics must cause little or no harm to the host. Some, such as penicillin, inhibit the synthesis of the bacterial cell wall; whereas others, such as the polymyxins, disrupt the bacterial cell membrane, a structure functionally distinct from the cell wall. Antibiotics also act by affecting bacterial protein synthesis (chloramphenicol, tetracyclines), nucleic acid metabolism, and intermediary metabolism of the bacteria.[1-4] The mechanisms that cause antibiotic neurotoxicity may differ considerably from the mechanisms of antibiotic action on microorganisms.

Adverse drug reactions may be: (1) toxic reactions related to excessive dosage, (2) side reactions due to an unintended pharmacologic effect of the medication, (3) allergic reactions, and (4) idiosyncrasies to the drug that are unrelated to dosage or allergy.[5,6] The mechanisms underlying the various neurotoxic effects are not fully understood, but the reactions are of different types. Among the neurotoxic effects are cochlear damage, vestibular damage, block of neuromuscular transmission, optic neuritis, seizures, arachnoiditis, peripheral neuropathy, and miscellaneous reactions.[7] Other reactions associated with non-antibiotic antimicrobial drugs such as the sulfonamides and isoniazid will not be discussed.

Cochlear Damage

Hearing loss is caused most often by derivatives of *Streptomyces* organisms, including dihydrostreptomycin, kanamycin, neomycin, vancomycin, viomycin, and to a lesser extent, streptomycin. Other antibiotics that cause auditory impairment include gentamicin, colistin, and framycetin.[8-10]

The hearing loss that results from antibiotic toxicity is due to degeneration in the organ of Corti and its sensory receptors. Hawkins and Lurie[11] explained the selective toxicity to the eighth cranial nerve of dihydrostreptomycin and neomycin on the basis of the special access of these antibiotics to the inner ear by way of cerebrospinal fluid and perilymphatic channels. This was demonstrated by the greatly increased severity and decreased latency of the ototoxic effect of moderate doses of parenterally administered streptomycin and dihydrostreptomycin, when supplemented by the intracisternal injection of minute amounts of the appropriate drug.

Engström and Kohonen,[8] studying the human cochlea, demonstrated that kanamycin, neomycin, and framycetin first damaged the outer hair cells at the basal end of the cochlea, the sensory endings for high-frequency hearing. The degree of destruction of the hair cells in the basal coil was directly related to dosage and length of treatment. Inner hair cells were damaged much later than outer ones and were first destroyed at the top coil of the cochlea. Damage to supporting elements also occurred with increasing dosage. Hawkins,[12] studying kanamycin in animals, was unsure whether the initial changes were in the hair cells or in the supporting cells of the organ of Corti. Degeneration of nerve tracts in the central nervous system has not been encountered without loss of sensory epithelium, thus indicating the peripheral origin of the toxic damage.[13]

*This paper was prepared under the supervision of members of the faculty of the Mayo Graduate School of Medicine.

Stupp and associates[14] have shown that the level of kanamycin in labyrinthine fluid increases more rapidly than the level in serum and is not directly related to the dosage. The maximal concentration in the inner ear is reached at the relatively small dose of 50 mg/kg, and the concentration is not increased by a dose five times greater. However, a significant increase in concentration of kanamycin in labyrinthine fluid is demonstrated if the higher dose is given for 10 to 20 days.

A major factor in the antibiotic concentration in plasma is the rate of excretion. Delayed excretion results in higher serum levels and increases the chance of adverse drug reactions.[10] Patients with pre-existing renal damage are more likely to experience toxic effects of drugs excreted by the kidney. Because all of the drugs previously mentioned, except framycetin, are nephrotoxic, renal impairment may develop during therapy.

Recent histochemical studies indicate that the ototoxic antibiotics probably impair glucose metabolism and interfere with the energy supply of the sensory cells in the inner ear.[10]

Clinically, cochlear damage due to antibiotic toxicity begins with loss of high-frequency hearing, the loss being demonstrable by audiometry.[7] Tinnitus or a feeling of fullness in the ear may precede this loss in about half the cases.[9] The hearing loss worsens to include the lower frequencies and can result in total deafness.[10] Once these changes occur, they are usually permanent, although a few patients have had return of partial hearing after cessation of kanamycin therapy.[15] The damage may occur after a latent period and may increase after the use of the antibiotic has been discontinued, especially when drug excretion is impaired. This is especially true with dihydrostreptomycin, but not with kanamycin.[9,15]

Although individual sensitivity may be a factor, dosage and duration of administration seem to be most important in the production of cochlear damage by antibiotics. Maximal dosage limits are recommended for most of these antibiotics in order to minimize the possibility of hearing loss. The likelihood of antibiotic ototoxicity is greatest in infants, the aged, dehydrated patients, and those with impaired renal function.[7] Hearing loss has occurred in infants of mothers treated with streptomycin during pregnancy.[16]

Ototoxicity may be associated with administration of these drugs by any route. It is generally recommended that combinations of ototoxic drugs not be given concurrently or in succession. In long-term therapy, such as for tuberculosis, intermittent administration is suggested.[7]

Vestibular Damage

Antibiotic-induced vestibular damage is closely related to cochlear toxicity. Streptomycin is the most common antibiotic that produces vestibular dysfunction, but most of the antibiotics that cause hearing loss may also lead to vestibular changes. Why streptomycin acts differently in predominantly affecting the vestibular sensory organs in the inner ear is unexplained. Streptomycin may also damage cochlear structures, resulting in hearing loss.[17]

Vestibular toxicity from streptomycin is directly related to dosage and duration of administration,[18] though individual sensitivity, rate of excretion, age, and state of hydration are also factors. The mechanism is unknown, although inhibition of glucose metabolism supplying energy for the end-organ cells by the drug has been suggested.[10] The vestibular damage is usually bilaterally symmetric, although asymmetric or even unilateral damage has been reported.[9]

Clinically, vestibular toxicity from streptomycin causes disturbance of gait and vertigo associated with head movements. Although the pathologic changes are apparently irreversible, symptoms often seem to gradually diminish, perhaps partly because of compensation by visual mechanisms.[7]

Block of Neuromuscular Transmission

An interesting peripheral neurotoxic effect of some antibiotics is blockade of neuromuscular transmission. Antibiotics that may do this are neomycin, streptomycin, dihydrostreptomycin, polymyxin A and B, kanamycin, colistin, viomycin, and paromomycin.[19,20]

The mechanism of neuromuscular transmission blockade is unclear. Elmqvist and Josefsson,[21] studying neomycin-produced neuromuscular block in laboratory preparations by extracellular and intracellular recording techniques, observed that the block was due to a

reduction in amplitude of the end-plate potential. This was caused, in part, by a decrease in sensitivity of the post-junctional end-plate membrane to the depolarizing action of acetylcholine. They also found that neomycin reduced the amount of acetylcholine released after stimulation of the motor nerve. This effect was antagonized by an excess of calcium ions. They believed the most likely explanation of the pre-junctional action of neomycin is that it, like magnesium, competes or interacts with calcium ions at some step in the release of acetylcholine. Brazil and Corrado,[22] studying neuromuscular transmission in dogs, noted many similar effects of magnesium ions and streptomycin.

Kubikowski and Szreniawski[23] reported that the depression of motor-nerve endings caused by several antibiotics is biphasic; there is a short initial phase of competitive blockade followed by a prolonged depolarization combined with calcium depletion. They stated that the same antibiotic probably could produce neuromuscular blockade by different mechanisms, depending on its duration and concentration in the vicinity of the end-plate.

Early clinical reports of antibiotic-induced neuromuscular blockade described respiratory depression after intraperitoneal and intrapleural administration of neomycin and streptomycin during surgery.[19] Gold and Richardson[24] reported the case of a 48-year-old woman who experienced ptosis, diplopia, and bilateral weakness in her shoulder girdle and arms within five hours after the intramuscular administration of colistin methanesulfonate (Coly-Mycin). Edrophonium chloride (Tensilon) reversed the weakness but had a variable effect on the ptosis. The symptoms occurred with a blood level of the antibiotic in the low therapeutic range and began to subside within eight hours after drug injection. The patient showed no evidence of myasthenia gravis on electrophysiologic studies during an antibiotic-free period.

The neuromuscular blocking action of the antibiotics previously mentioned may be potentiated by drugs such as ether or other anesthetic agents, muscle relaxants, sedatives, or narcotics.[24,25] The antibiotics may aggravate the weakness in patients with myasthenia gravis.[26]

Treatment of antibiotic-induced neuromuscular blockade includes support of respiration, cessation of therapy with the implicated antibiotic and possible potentiating drugs, and use of neostigmine or calcium or both.[25]

Optic Neuritis

Optic neuritis occurs occasionally in association with chloramphenicol or streptomycin therapy, apparently due to a deficiency of vitamin B, possibly of pyridoxine.[7,27-29] Some authors have questioned the cause-and-effect relationship of antibiotics and optic neuritis, stating that the toxic phenomenon may be related to the basic disease process or to an associated nutritional deficiency.[30]

The optic neuritis causes loss of visual acuity, constriction of visual fields, scotomata, papilledema, and retinal hemorrhages. Usually, though not always, vision improves when the use of the drug is discontinued and therapy with vitamin B is given concomitantly. Cocke[27] has reported possible benefit with prophylactically administered pyridoxine and vitamin B_{12}, given with chloramphenicol, in a patient who had cystic fibrosis and who had had two previous episodes of chloramphenicol-induced optic neuritis.

Seizures

The irritating effects of penicillin on the central nervous system, first described by Johnson and Walker[31] after intraventricular administration in a case of meningitis, may consist of muscular hyperirritability, myoclonic jerking, generalized seizures, coma, and death.[32,33]

Penicillin rarely crosses the blood-brain barrier in the normal person, but when meningeal inflammation is present, higher concentrations of the drug in the cerebrospinal fluid occur with systemic administration.[34] Neurotoxicity rarely occurs unless the dose exceeds 60 million units per day,[35] or unless renal insufficiency is also present.[36] Direct administration of penicillin into the cerebrospinal fluid is more likely to cause neurotoxicity; this is particularly true of intraventricular or intracisternal injections.[32,37] Weinstein[33] recommends that dosages above 30,000 units should not be injected into the subarachnoid space in adults, and that lesser dosages should be used

in children.

Cycloserine, in doses greater than 1 gm/day, has been reported as causing myoclonic jerking and epileptiform seizures. These effects are rapidly reversible after the use of the drug is discontinued.[30,38]

Arachnoiditis

Arachnoiditis with radiculopathy and myelopathy may occur as a complication of the intrathecal injection of any chemical agent, including antibiotics.[37,39,40] Recommendations to prevent or minimize this neurotoxic reaction of amphotericin B, administered intrathecally for fungal meningitides, include use of small, well-controlled amounts of the drug, intrathecal administration of corticosteroids prior to the use of the antibiotic, and alteration of intrathecal injection sites—lumbar and cisternal areas.[40]

Fortunately the intrathecal use of antibiotic agents is rarely necessary in the treatment of bacterial meningitis now, unless the physician is confronted with a *Pseudomonas* meningitis that requires the use of polymyxin, or a severe pneumococcal meningitis that requires the use of penicillin. In tuberculous meningitis, intrathecally administered streptomycin is no longer used, but in previous years this drug has caused arachnoiditis in some patients.

Peripheral Neuropathy

Peripheral neuropathy has occurred during treatment with streptomycin, dihydrostreptomycin, neomycin, kanamycin, chloramphenicol, polymyxin B, colistin, and amphotericin B. Some of these toxic neuropathies may be related to depletion of pyridoxine. They are sensorimotor in character and reversible if the antibiotic therapy is discontinued soon after the onset of symptoms.[7,29]

Circumoral and distal paresthesias may develop during therapy with streptomycin, dihydrostreptomycin, neomycin, kanamycin, polymyxin B, and colistin. Usually these symptoms are ameliorated even when therapy is continued, and they generally disappear when the therapy is stopped.[7,41]

Mononeuropathy occurs from inadvertent injection of an antibiotic into a peripheral nerve, producing chemical injury that may persist indefinitely.[18]

Miscellaneous Reactions

Nonspecific reactions such as headache, insomnia, weakness, and drowsiness may occur while a patient is receiving antibiotics. Penicillin and cycloserine may be associated with personality changes and acute psychoses.[7,38]

Tetracycline therapy in infants has been associated with increased intracranial pressure; the pressure disappears when the use of the drug is discontinued. No relationship was noted between the occurrence of bulging fontanelle and either the dose or the length of therapy.[42]

Conclusion

Antibiotic neurotoxicity results from factors that influence the metabolism, neutralization, and excretion of antibiotics; these factors include the specific drug, route of administration, dose and duration of therapy, and the physiologic deficit of the patient.[43]

The most common neurotoxic effect is damage to the auditory and vestibular apparatus, generally by antibiotics derived from *Streptomyces* organisms. Usually these reactions are related to dose and duration of treatment. Disturbed physiologic functions of the patient, such as impairment of renal function, are important factors in determining the dose that a patient may tolerate.

No brain is stronger than its weakest think.—Tom Masson

OMNI-TUSS® b.i.d.

. . . **because** OMNI-TUSS is indicated for cough associated with upper respiratory tract infections, bronchitis, bronchiectasis, bronchial asthma, emphysema, sinusitis and rhinitis, hay fever, or other allergic conditions. Any of these conditions may exhibit the general symptom syndrome—coughing, wheezing, bronchospasm, and tenacious mucus—which may benefit from the antitussive, bronchodilative, antihistaminic, and expectorant action of Omni-Tuss.

The therapeutic usefulness of Omni-Tuss is enhanced by a unique resin complex formulation providing the clinically desirable advantages of: (1) uniform drug availability throughout an extended period, (2) 8 to 12 hours of symptomatic control, (3) minimal dosage requirement, (4) minimal side effects.

Economical, efficient **b.i.d.** dosage—extremely well-tolerated by children, 6-12, and adults.

'Omni Tuss' Suspension: Each teaspoonful (5 cc.) contains 10 mg. codeine (Warning: May be habit-forming), 5 mg. phenyltoloxamine, 3 mg. chlorpheniramine, 25 mg. ephedrine, all as cation exchange resin complexes of sulfonated polystyrene, and 20 mg. guaiacol carbonate.

Available on prescription only. Class X exempt narcotic. Permissible on oral prescription.

Dosage: *Adults:* 1 teaspoonful (5 cc.) q12h.
Children (6-12 *years*): ½ teaspoonful q12h.

Side Effects: Minimal, but when encountered may include jitteriness, nausea, drying of mouth, insomnia, constipation, which disappear upon adjustment of the dose or discontinuance of treatment.

Precautions and Contraindications: For complete detailed information, refer to package insert or official brochure.

Strasenburgh Laboratories Division
Wallace & Tiernan Inc., Rochester, N.Y.

When it's more than a bad cold

your patient can feel better while she's getting better

Achrocidin®

Tetracycline HCl—Antihistamine—Analgesic Compound

Each tablet contains: ACHROMYCIN® Tetracycline HCl 125 mg.; Phenacetin 120 mg.; Caffeine 30 mg.; Salicylamide 150 mg.; Chlorothen citrate 25 mg.

In tetracycline-sensitive bacterial infection complicating respiratory allergy, ACHROCIDIN brings the treatment together in a single prescription—prompt relief of headache and congestion together with effective control of the organisms frequently responsible for complications leading to prolonged disability in the susceptible patient.

For children and elderly patients you may prefer caffeine-free ACHROCIDIN Syrup. Each 5 cc contains: ACHROMYCIN (Tetracycline) equivalent to Tetracycline HCl 125 mg.; Phenacetin 120 mg.; Salicylamide 150 mg.; Ascorbic Acid (C) 25 mg.; Pyrilamine Maleate 15 mg.

Contraindications: Hypersensitivity to any component.

Warning: In renal impairment, since liver toxicity is possible, lower doses are indicated; during prolonged therapy consider serum level determinations. Photodynamic reaction to sunlight may occur in hypersensitive persons. Photosensitive individuals should avoid exposure; discontinue treatment if skin discomfort occurs.

Precautions: Drowsiness, anorexia, slight gastric distress can occur. In excessive drowsiness, consider longer dosage intervals. Persons on full dosage should not operate vehicles. Nonsusceptible organisms may overgrow; treat superinfection appropriately. Treat beta-hemolytic streptococcal infections at least 10 days to help prevent rheumatic fever or acute glomerulonephritis. Tetracycline may form a stable calcium complex in bone-forming tissue and may cause dental staining during tooth development (last half of pregnancy, neonatal period, infancy, early childhood).

Adverse Reactions: *Gastrointestinal*—anorexia, nausea, vomiting, diarrhea, stomatitis, glossitis, enterocolitis, pruritus ani. *Skin*—maculopapular and erythematous rashes; exfoliative dermatitis; photosensitivity; onycholysis, nail discoloration. *Kidney*—dose-related rise in BUN. *Hypersensitivity* reactions—urticaria, angioneurotic edema, anaphylaxis. *Intracranial*—bulging fontanels in young infants. *Teeth*—yellow-brown staining; enamel hypoplasia. *Blood*—anemia, thrombocytopenic purpura, neutropenia, eosinophilia. *Liver*—cholestasis at high dosage.

Upon adverse reaction, stop medication and treat appropriately.

Grand Rounds

Pernicious Anemia vs. Gastric Carcinoma*

NEIL R. HOFFMAN, M.D.†
Minneapolis, Minnesota

PERNICIOUS ANEMIA is a chronic disease, generally affecting people past middle age. It usually produces hematologic, gastrointestinal, and neurological manifestations. Before the discovery of liver therapy, its course, even though interrupted by exacerbations and remissions, was uniformly fatal; thus the name "pernicious anemia" was coined. Now with specific therapy this disease is virtually never fatal, but the name, pernicious, remains.

The clinical features of pernicious anemia were first described by Addison in 1855. Fenwick, in 1880, suggested that inadequate digestion and utilization of food was the basic problem.[1,2] Minot and Murphy, in 1926, demonstrated the value of liver therapy in patients with pernicious anemia,[3] and Castle's experiments in 1929 brought into focus the etiologic concepts in regard to intrinsic and extrinsic factor in the pathogenesis of this disease.[4]

Incidence

Although this disease is seen chiefly in Caucasians and is more common in persons of Scandinavian ancestry, it occurs in all peoples. Its incidence in Negroes is low but not as low as previously thought.[5] It is a disease of adult life and, in this country, more common in women than men.

Pathogenesis

The mucosal (parietal cell) glands of the fundus of the stomach secrete a glycoprotein known as intrinsic factor, which is necessary for the absorption of vitamin B_{12}.[22] The normal amount of absorption in the adult is 1 to 2 mcg/day. Loss of intrinsic factor secretion leads to the inability of the ileum to absorb vitamin B_{12}, and in turn to a B_{12} deficiency state. When the capacity

*Presented as a Medical Grand Rounds at Hennepin County General Hospital, May 7, 1968.
†Currently on active duty, United States Naval Hospital, Oakland, California.

to absorb vitamin B_{12} is abruptly lost in an otherwise healthy individual (e.g., after total gastrectomy), the clinical manifestations associated with B_{12} deficiency usually develop in about three years.

Vitamin B_{12} is found in many tissues of the body, the highest concentration being in the liver. It is interesting that there is no good evidence that B_{12} shifts from the liver to other organs when a deficiency is present; in fact, in complete relapse of pernicious anemia, the B_{12} content of the liver when measured is only 10% of normal.[22] This suggests that in pernicious anemia there is some block of release of B_{12} from the liver.

Clinical Manifestations

The classical diagnostic triad in pernicious anemia is weakness, sore tongue, and parasthesias; usually numbness and tingling of the extremities. However, with diagnostic tests to help us detect the disease earlier, the classic findings may be absent.[6] Weakness seems to be the most common presenting symptom, and glossitis is present in about 10% of cases. With severe anemia, the skin's color turns to a light lemon yellow. Very often there will be premature greying or blond hair. Even though there is a thrombocytopenia, petechiae are unusual. Vitiligo may also be present.

Fever elevation up to 102° is not uncommon and generally remits when treatment is started. Semi-solid bowel movements, two to three per day, are a common finding. The liver is usually slightly enlarged, and splenomegaly is reported in various series from 3% to 40%.[7]

Neurologic involvement from pernicious anemia is commonly seen.[1,5] Complaints usually consist of generalized weakness, numbness, and tingling of the extremities that may lead to difficulty in navigating. Peripheral nerve degeneration as well as spinal cord degeneration may occur.[8] Numbness and a "glove-stocking" type of paresthesia may develop as a result of peripheral nerve damage. The spinal cord degeneration usually starts in the posterior columns, but then goes on to involve the lateral columns as well. When the distal and lateral columns are both involved, ataxia and some spasticity may be present. Altered mentation* is usually noticeable, with irritability, apathy, memory loss, and somnolence being the most common symptoms. Loss of vibratory sense and position sense is frequently noted.

Laboratory Findings[1,5]

Peripheral Blood

The peripheral blood findings generally include all the formed elements: red cells, white cells, and platelets. The red cells usually show macrocytic changes. The cells may be oval in shape and, due to basophilia, stain a blue-grey color. Poikilocytosis is usually present. Generally the more pronounced the anemia the more bizarre the shapes that are seen. The cells, whether small or large, normal or bizarre, are usually well filled with hemoglobin and generally do not have a central pale zone. Occasional Howell-Jolly bodies may be found. Reticulocytes are usually not seen, except in response to therapy. It is an error to assume that the red blood cells in pernicious anemia are supersaturated with hemoglobin; the concentration of hemoglobin in these cells is the same as in normal red cells, about 32% to 36%.

The leukocytes may be larger than normal and multi-segmented. These lobes may have bizarre shapes and the chromatin bridges connecting them

*See Test Your Word Score Page 1583.

may be thin and stringy. The nuclear matter may appear looser than normal, and the cytoplasmic granulation may be more acidophilic and larger than normal. These changes in the white cells may be the first peripheral blood changes to occur in pernicious anemia. There is usually an absolute neutropenia as well as a relative lymphocytosis. Immature cells of the myeloid series may be present, but are usually only about 1% of all the leukocytes seen. Eosinophilia is seen occasionally.

The platelets are generally decreased in number and, as with the leukocytes, bizarre shapes may be noted.

Bone Marrow

The volume of the marrow in pernicious anemia is usually increased by the replacement of fat along marrow cavities and by the increased number of cells. Instead of the normal erythrocyte to myelocyte ratio of 1:4, the red cell hyperplasia may shift this to 1:1. Instead of the usual normoblastic proliferation of the red cell series, one sees a megaloblastic proliferation. The megaloblasts may be distinguished by their large size and their delicate nuclear chromatin; they may have very basophilic cytoplasm and not appear at all like members of the erythroblastic series, which generally lack cytoplasmic granulation and have large central neuclei and irregular borders. There are generally more megaloblasts than normoblasts. Abnormal leukopoiesis is also seen in the bone marrow of patients with pernicious anemia. There is usually an increase in myeloid leukocytes, and many large leukocytes may be noted. Megakaryocytes, besides being reduced in number, may also be abnormal in configuration.

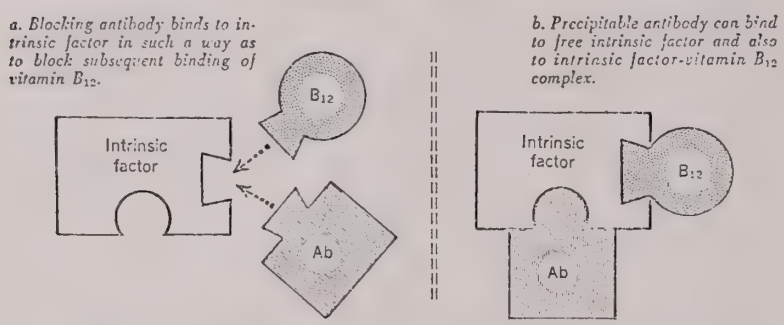
Other Laboratory Abnormalities

There is also an inability to concentrate urine; the specific gravity is usually low and fixed. During relapse the serum alkaline phosphatase is low, while the serum lactic acid dehydrogenase activity is markedly increased.[8] The serum cholesterol is lower in relapse than in remission. There is usually a negative nitrogen balance in relapse, with decreased colloidal osmotic pressure of plasma, and mild water retention. Hypogammaglobulinemia may also be present.[1] There is generally a slight increase in serum bilirubin.

Gastric Findings

Gastrointestinal symptoms do not seem to be a common complaint in patients with pernicious anemia, although abnormalities of the gastrointestinal tract are usually seen. Histamine-fast achlorhydria is almost always found, except perhaps in infants and adolescents. The gastric mucosa is generally atrophic, and there is an increased incidence of gastric polyps. Small bowel biopsies in patients with pernicious anemia in relapse show a decrease in mitoses and a shortening of villi, as well as megaloblastic changes in the epithelial cells.[10] Administration of vitamin B_{12} will revert these changes to normal in about two months.

Basis for Auto-immunity



In attempting to determine an etiologic basis for pernicious anemia, much work has been done on the immunologic aspects of this disease. It is well established that acquired pernicious anemia is due to an inadequate amount or absence of intrinsic factor.[4,5] On gastric biopsy there is usually a reduction in the parietal cells, which in man are responsible for the secreting of intrinsic factor. In an attempt to differentiate these findings from a "pure"

atrophic gastritis, various screening tests were done to see if the two could be differentiated. It was found that patients with pernicious anemia have a high incidence of antibodies specifically against the parietal cell.[12,13,14] Ninety percent of patients tested had antibodies to the parietal cells, whereas patients with a pure type of atrophic gastritis showed an absence of antibodies either to the parietal cells or to intrinsic factor.[12] Herburt has reported that 60% of patients with pernicious anemia have antibodies against intrinsic factor, 90% against the parietal cell, and about 50% against the thyroid gland.[13,15,18]

The high incidence of antibodies detected in patients with pernicious anemia, in combination with histologic features of chronic inflammation and atrophic gastric mucosa, suggest that the disease may be an auto-immune disorder. This is in part substantiated by the high incidence of thyroiditis and myxedema in pernicious anemia.[16,20,21,23] No one, however, has established that these antibodies are harmful to gastric mucosa.[13] Antibodies to intrinsic factor have also been found in the saliva of patients with pernicious anemia.[17]

There are two types of antibodies to intrinsic factor that have been found in patients with pernicious anemia.[12,17,19] One seems to be directly related to intrinsic factor, while the other is directed against the parietal cell. The blocking antibody combines with intrinsic factor in such a way as to preclude the combination with B_{12} (Figure 1). The precipitable antibody can combine with intrinsic factor alone or in combination with B_{12}, and can then be precipitated by various gamma globulin precipitants.

Two functional classes of antibody to intrinsic factor.

Figure 1

Evaluation of Pernicious Anemia at Hennepin County General Hospital from 1961-1967

During the seven-year period from 1961 through 1967 a total of 81 patients were admitted to Hennepin County General Hospital with proven pernicious anemia. Of these 81 patients, 48 were being seen for the first time, and the diagnosis of pernicious anemia was new; the other 33 had been followed here for an average of 10.7 years. Our series included 18 males and 33 females. The age range at the time pernicious anemia was diagnosed was 33 to 87, the mean age being 74. The diagnosis was established by peripheral blood morphology, abnormal Schilling test, or abnormal and characteristic bone marrow. At least two of the above criteria had to be positive for the

diagnosis to be accepted. All of the cases responded to administration of vitamin B_{12} except one patient, who also exhibited a relapse of monocytic leukemia.

Hemoglobin determinations at the time of diagnosis ranged from 2.9 to 10.9 grams. Bone marrow examinations were done in 33 patients, and all the interpretations were consistent with the changes seen in pernicious anemia. Decreased-to-absent iron stores were noted in over 75%.

Weakness of insidious onset was noted in almost all of our patients as an initial complaint. Leukopenia and thrombocytopenia were present in over three fourths. None exhibited any bleeding abnormalities. The maximal reticulocyte response to vitamin B_{12} occurred between the fourth and fifth day, the highest response being 39.8%, the lowest 2%. The patient with a 2% response had acute leukemia in relapse at the same time his pernicious anemia was noted to be in relapse. The peripheral smear was considered to be diagnostic in 37 of the 48 new patients in whom it was done. The Schilling test was made in 28 patients and was below 3% excretion in 26.

Six of our patients had co-existing carcinomas (Table 1). Two had hematologic malignancies; two, prostatic malignancies; one, colon carcinoma, and one, multiple myeloma. Two had gastric polyps, detected on gastroscopy; one was not noted on barium x-rays and three were hypothyroid. None had a diagnosis of carcinoma of the stomach.

Relationship of Pernicious Anemia to Gastric Carcinoma

That persons afflicted with pernicious anemia have a greater chance of developing cancer of the stomach than the general population has been suggested by several studies.[24,25,26] This increased incidence of gastric carcinoma is reported to be 1% to 18% higher than in the general population. Hitchcock, in following 1,399 patients for nine years who were achlorhydric but did not have pernicious anemia, concluded the incidence of gastric carcinoma to be 0.9% higher than in the normal population. He also followed 77 patients with pernicious anemia, of whom 5.2% later developed carcinoma of the stomach.[25] Patients over 50 years of age with pernicious anemia were expected to have an 18.3% increased incidence of gastric carcinoma, over the national average. It was therefore concluded and generally accepted that patients with pernicious anemia had a statistically greater chance of developing cancer of the stomach and should be closely followed.

The above studies were done from 1925 to 1950, when the general incidence of gastric cancer was much higher than now. While the incidence is

presently falling, the reported incidence of pernicious anemia has remained constant. In studying the etiologic factors in cancer of the stomach in England, Maddock reported the following:[27]

1) The mortality for persons with pernicious anemia was the same as for the general population.
2) In comparing two endemic areas, one having a high incidence of stomach cancer, the other with an average incidence, the incidence of pernicious anemia in the two areas was the same.

He therefore concluded that statistically the two diseases do not seem to be related. In our study of 81 patients with pernicious anemia over a seven-year period there were no stomach cancers noted. It would seem that if the two diseases were closely related, and that if there is in fact an almost twenty percent increase over the expected incidence of stomach cancer, our series would also bear this out, especially since the average age of our patients was 74 years. The fact that our series is devoid of cancer of the stomach, the fact that the incidence of cancer of the stomach is declining while the incidence of pernicious anemia is relatively constant, and the fact that the only recent study of these two diseases shows no correlation, raises the question whether patients with pernicious anemia actually have an increased incidence of cancer of the stomach.

It was initially suggested by Rigler that patients with pernicious anemia should have annual radiographic stomach examinations, but this was found to be impractical and has been generally discarded.[28,29,30] The incidence of carcinoma of the stomach in persons over 50 years of age, between 1953 and 1964, at the Cancer Detection Center of the University of Minnesota, was one positive examination per 1,900 examinations, and the incidence continues to decline.[31]

Treatment[1,5,32]

The treatment of pernicious anemia is the administration of vitamin B_{12}. Dosage schedules are as varied as the clinicians treating this disease; as little as 1 mcg. of B_{12} per day can bring about clinical recovery.[22] Treatment, however, should attempt to restore the body stores of B_{12}, in addition to inducing a clinical response. The average deficit in a person with pernicious anemia is about 2,000 to 3,000 mcg. An additional consideration in treatment should be the oral administration of iron, especially if the iron stores are low. As one starts to convert from a megaloblastic to a normoblastic marrow, initially the hemoglobin may fall slightly. As effective erythropoiesis is attained, large amounts of body iron are needed for red blood cell production. Low available iron may decrease the response. There are oral forms of vitamin B_{12} with or without intrinsic factor; however, the mainstay of therapy remains parenteral administration. Since the basic defect in pernicious anemia is permanent, maintenance therapy on a regular schedule is necessary.

Case Report

Case 1

A 56-year-old white female of German-English descent was admitted to the hospital on January 14, 1968, as a disposition problem. She had no specific complaints other than muscle aches and generalized weakness. She had not been strong enough to leave her apartment for three weeks, and for one week was confined to bed due to profound weakness.

On admission the patient was noted to be somnolent, confused as to time and place, and appeared older than her stated age of 56. She had blue eyes and white silky hair, and her skin had decreased turgor, with a yellow tinge. There was minimal periorbital edema. Position

and vibration sense was poor. A faint systolic ejection murmur was noted, and her liver was palpable 3 to 4 cm. below the costal margin and was not tender.

Hospital Course

On admission her hemoglobin was 2.6 gm %, RBC 610,000, WBC 4,500, with a normal differential, and a platelet count of 15,000. The peripheral blood smear showed macrocytosis, and moderate numbers of six-lobed neutrophils were present. The diagnosis of pernicious anemia was suspected, and due to her low hemoglobin two units of whole blood were given slowly, bringing her hemoglobin up to 4.4 gm%. The next morning her strength was slightly improved, but her sensorium was still clouded.

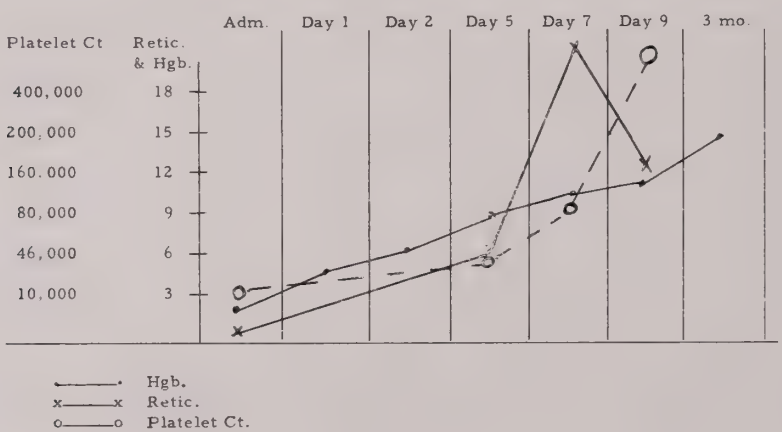
Laboratory Findings

Chest film: Cardiac enlargement. Stool guaiacs negative throughout her course. VDRL negative. Blood chemistries on admission revealed the following abnormalities: K = 3.0, Cl = 97, albumin = 3.5, total bilirubin 1.6, cholesterol 112. PBI 6.1. Shilling test showed the following:

a) without intrinsic factor
urine excretion at 24 hours 3.7%
blood 1.62 mg/ml (normal 4.8 ± 1.6)

b) with intrinsic factor
plasma 0.238%/1% body weight
(normal 0.18 – 1.8%)

Serum Iron 245 mcg %
Iron Binding Capacity 263
% Saturation 93%



Gastroscopy and X-ray Findings

Atrophic gastritis, with a small polypoid lesion in the mid-stomach. Stomach x-rays showed a normal mucosal pattern with no gross abnormalities. There was a small hiatus hernia present with some reflux. The polypoid lesion noted on gastroscopy was not seen.

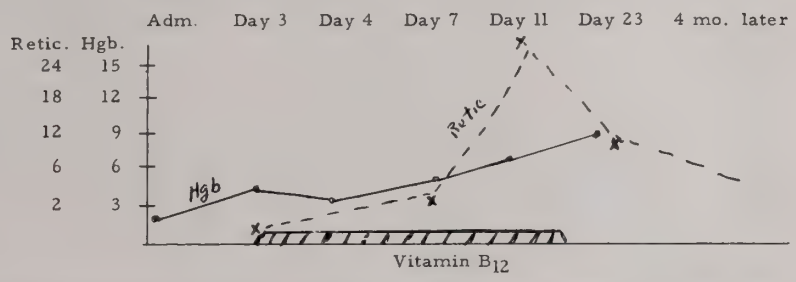
Bone Marrow

Hyperplastic marrow with no marrow fat. Sheets of megaloblasts were noted. There was no stainable iron seen.

On the fifth hospital day the patient was more alert and oriented. Her improvement was progressive and she was discharged on the 11th hospital day.

Case 2

A 79-year-old white male was admitted with a three-month history of progressive weakness. Hemoglobin in 1961 was 11.0–13.6 gm%.



Physical Examination

Cachectic-appearing, confused white male with sallow yellow skin. There was bilateral axillary adenopathy. The chest was clear to ascultation. There was a Grade II systolic ejection murmur at the left sternal border. The liver was enlarged about 4 cm. below the costal margin and non-tender.

Laboratory Findings

Admission

Hgb. 2.9 gm%
Hct. = 9%
RBC 810,000 million
WBC 1,500 with 38% PMN's and 61% lymphocytes
Platelets = 10,000
Serum iron 186 mcg%
Iron binding capacity 212
% Saturation 88%
LDH 2713 units
PBI 5.5 mcg%
Schilling test: urine excretion 0.42% in 24 hours
Serum B_{12}—non-detectable
Total bilirubin 1.6 mg%
Coombs—negative
Gastric analysis—no free acid
Bone marrow—megaloblastic changes noted, with decreased iron stores.

The patient was treated with B_{12} and iron and responded slowly. He now has a normal hemoglobin, is oriented, and appears to be in normal health.

Mirabile Dictu*

Sir Hans Sloane, who saved the Chelsea Physic Garden for the Apothecaries and Virginia, was the first physician to be made a baronet. He was a founder and later President of the Royal Society. . . . He was also for many years President of the Royal College of Physicians.

Sir Hans, like many doctors, was passionately interested in curiosities. He was particularly fond of giants. He studied their bones. There was the shin-bone of the "noble and puissant lord, the Chevalier Ricon de Vallemont." This was over four feet long, so the Chevalier must have been more than 17 feet tall. There was the giant Bucart, who was 22½ feet high according to similar calculations. Better still was Theutobochus Rex, a skeleton disinterred in 1613 and measuring 25 feet. Sir Hans concluded sadly that pretty well all these bones belonged to whales, elephants, mastodons and other animals.

Later students have taken the same view. As measurements have become more precise giants have become less gigantic. According to a nice calculation Adam was 123 feet high and Eve 118 feet, which suggests that the serpent must have been something out of this world.†

†Harvey Graham: A Doctor's London, 1952.

Nothing else I've tried seems to work, so I decided to give you a crack at it.

Some U.R.I. patients are more miserable than others.

That's why we make Novahistine® tablets in two different formulations.

And let you control the dosage.

With Novahistine LP tablets and Novahistine Singlet tablets you have the range and flexibility of decongestant dosage that lets you prescribe for the needs of the individual patient.

Novahistine LP tablets are most useful for relief of nasal congestion in patients without pain or fever.

Novahistine Singlet tablets, which provide analgesic-antipyretic effect, as well as decongestant action, are indicated for upper respiratory infections accompanied by pain, aches and fever.

Whether you prescribe Novahistine LP or Novahistine Singlet, a total daily dose of 3 or 4 tablets will usually provide effective, continuous relief.

Use cautiously in patients with severe hypertension, diabetes mellitus, hyperthyroidism or urinary retention. Caution ambulatory patients that drowsiness may result.

Each Novahistine LP tablet contains phenylephrine hydrochloride, 25 mg.; and chlorpheniramine maleate, 4 mg.

Each Novahistine Singlet tablet contains phenylephrine hydrochloride, 40 mg.; chlorpheniramine maleate, 8 mg.; and acetaminophen, 500 mg.

Dermatology

Alopecia Areata

ALOPECIA IS a term derived from the Latin word alopex, meaning fox. This animal is known to suffer mange with resulting bald areas. Areata simply means *limited* or *circumscribed area.*

Alopecia areata is one of the most common types of hair loss seen by the physician. The cause is unknown. From time to time various factors have been implicated, such as dental infections, errors in visual refraction, endocrine dysfunction, toxins, and direct contagion. Currently, the most popular concept is that of an emotional disturbance underlying alopecia areata. As yet none of these possibilities has been proved.

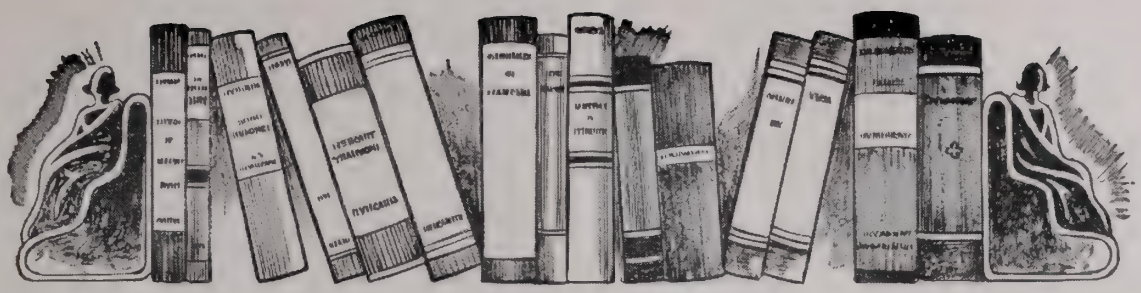
In most instances the diagnosis is easy, as the disease is characterized by one or more circumscribed areas of hair loss (Figure). The disorder is most frequently noted on the scalp, although any hairy area may be affected. Several descriptive terms are used with respect to the extent of the process. Alopecia totalis refers to involvement of the entire scalp, while alopecia universalis denotes the loss of all body hair. Alopecia areata may occur at any age, although it is most frequent during the first to fourth decades. The disease has been noted in all races and shows approximately equal sex distribution. At times this condition has been observed in several members of the same family. In these familial cases inheritance appears to be dominant with incomplete penetrance.

Clinically, the bald areas develop rapidly (within several days). Usually only one area of hair loss is noted at first, though on close inspection numerous

Figure

small areas may be present. There is no site of predilection; vertex, parietal, occipital and temporal regions may all be affected. As a rule, the process does not begin at the margin of the scalp. The area of hair loss enlarges by peripheral extension, and new areas may appear which then enlarge and may join the other areas, resulting in an irregular pattern. The skin in the affected areas is smooth and glossy. While sensation and/or redness is often noted, atrophy does not occur. Centrally in the areas of baldness no hair is visible; however, at the periphery one sees short hairs which are atrophied at their proximal portion while thickened and dark distally. These are called exclamation point hairs and are of diagnostic importance. When these hairs are seen at the periphery of a patch of alopecia it is evidence that the process is extending. In addition, longer hairs in the vicinity of the involved area frequently come away with gentle pulling.

At times nail changes may occur with alopecia areata, such as pits, ridges, furrows, and loss of the nail itself. Other rare findings associated with this condition include intestinal polyposis, thyroid disease, scleroderma and vitiligo.



Differential diagnosis is usually not difficult. However, at times several other disorders must be brought under consideration. Non-inflammatory ringworm of the scalp may resemble alopecia areata. In this affection one usually sees scaling and some degree of erythema, which is absent in alopecia areata. Occasionally, Wood's light examination culture and microscopic study of the hairs must be made to differentiate the two disorders. Impetigo or other bacterial infections may result in localized areas of hair loss; here inflammation and crusting are present along with prompt regrowth of hair after the process is controlled. Trichotillomania (self-inflicted removal of hair) usually does not show total baldness in the involved areas, and many short broken hairs are commonly present. The cicatricial alopecias such as lupus erythematosus, folliculitis decalvans and pseudo-palade all show atrophy as well as varying degrees of inflammation. Syphilitic (moth-eaten) alopecia may cause difficulty; here history, general physical examination and serologic tests are important in the differentiation from alopecia areata.

Prognosis in alopecia areata is not always easy. If the areas of involvement are few, regrowth may occur within four to 12 months. If the process is extensive, such as alopecia totalis, or if there are numerous areas, chances for regrowth are less favorable. Also, the longer the disease remains active, the less favorable is the prognosis. Of those patients recovering approximately 25 to 30 percent will have recurrences; the more frequent these recurrences, the poorer the prognosis.

Treatment of alopecia areata is generally unsatisfactory. Therapy consists of stimulatory measures such as strong ointments and ultraviolet radiation. These measures are probably based upon the concept that stimulation of hair follicles in certain animals has been proven to induce hair growth, but no such proof exists for the human hair follicle. General supportive measures, as well as topical and intra-lesional steroids, may be used. Steroids may induce hair growth, but when they are discontinued, the hairs will often be shed. This disorder warrants further study concerning etiology as well as treatment.

CURE FOR CANCER. A NATIONAL GOAL. Solomon Garb, M.D., Professor of Pharmacology, and Associate Professor of Community Health and Medical Practice, University of Missouri, School of Medicine, Pages 303, Springer Publishing Company, Inc., New York, N. Y. 1968.

Doctor Garb analyzes current cancer research. It is time, he says, to direct our resources toward a national goal aimed at cure or control of cancer, particularly since the death rate has risen in spite of the availability of many anti-cancer drugs.

The author comments upon the organization and budgeting of a national cancer research program, the nature of cancer, screening of anti-cancer materials, vaccines against cancer, spontaneous, induced, and transplanted cancer, genetic and molecular approaches to malignant neoplasms. Reasons are presented for a more intense study of plant material, bacteria and bacterial products, as well as sources from the sea such as extracts from the common clam. Surgical and radiotherapeutic measures are discussed. It is pointed out that cancer does not tend to regrow around the suture line when iodized sutures are used; also that radiation treatment cures some cancers, but that how this happens is still conjectural. While Burkitt's lymphoma and certain leukemias in children seem to be virus-linked, there is as yet no data showing that viruses are causally related to other human cancers.

The opinion is expressed that valuable contributions in cancer research can be made by veterinarians, pharmacists, dentists, and general biologists.

In the chapter "Leukemias and Ascorbic Acid" Dr. Garb advances the postulate that "some of the more distressing and dangerous symptoms of leukemia may be due to a relative deficiency of ascorbic acid (vitamin C)." While the ascorbic acid body level in health is about four grams, and one gram of this is held by the leukocytes tissue, subsaturation may result from a large volume of leukemic cells hoarding the vitamin and thus giving rise to symptoms resembling scurvy. Up to nine grams may be needed to establish a normal ascorbic acid balance. Barkham and Howard (Biochem. J. 70:163, 1958), for example, had to give approximately 15 grams of vitamin C to produce saturation. Whether ascorbic acid balance enhances the effectiveness of chemotherapeutic agents should be vigorously studied. This reviewer has observed beneficial effects from large daily doses of four to five grams of ascorbic acid in leukemic states complicated by scurvy.

Because Dr. Garb has packed a wealth of provocative data into 303 pages, it should be worth while for cancer researchers and allied scientists to read the booklet from cover to cover.

INTERNAL MEDICINE BASED ON MECHANISMS OF DISEASE, Peter J. Talso and Alexander P. Remenchik, Editors; C. V. Mosby Company, 1968; 797 pages; Price: $17.50.

Thirty-one contributing authors have written chapters in the first edition of this textbook of internal medicine. Although the title would suggest that the text is devoted to the abnormal physiology of disease, the book is mainly devoted to clinical aspects of diagnosis and treatment of the major diseases encountered in internal medicine. The first two sections of the book consisting of thirteen chapters are devoted to a discussion of internal medicine as a science and an art and the basic mechanisms of selected important disease states which apply in a number of specific diseases. The remainder of the book is devoted to discussion of the clinical aspects of diagnosis, therapy, and pathophysiology of the major diseases of the heart and blood vessels, the respiratory tract, the digestive system, and the endocrine system. In the last section the clinical aspects of diseases of the kidney, blood, musculoskeletal system and neurological and psychiatric disorders are presented.

The text is clearly written and reasonably well illustrated and contains key references to the medical literature for readers who wish to go into each subject in greater depth. Although the discussions in the various sections might be disappointing to the investigator in the field and the highly trained specialist, the material presented is quite comprehensive and will be useful to medical students, interns, residents, and general internists in the management of most problems encountered in the practice of internal medicine.

The book is recommended to medical students, house officers and physicians practicing general internal medicine as a good, well written text which will be useful along with one of the larger more comprehensive general textbooks of internal medicine.

the antacid puzzle

In peptic ulcer:

solved by Mylanta®

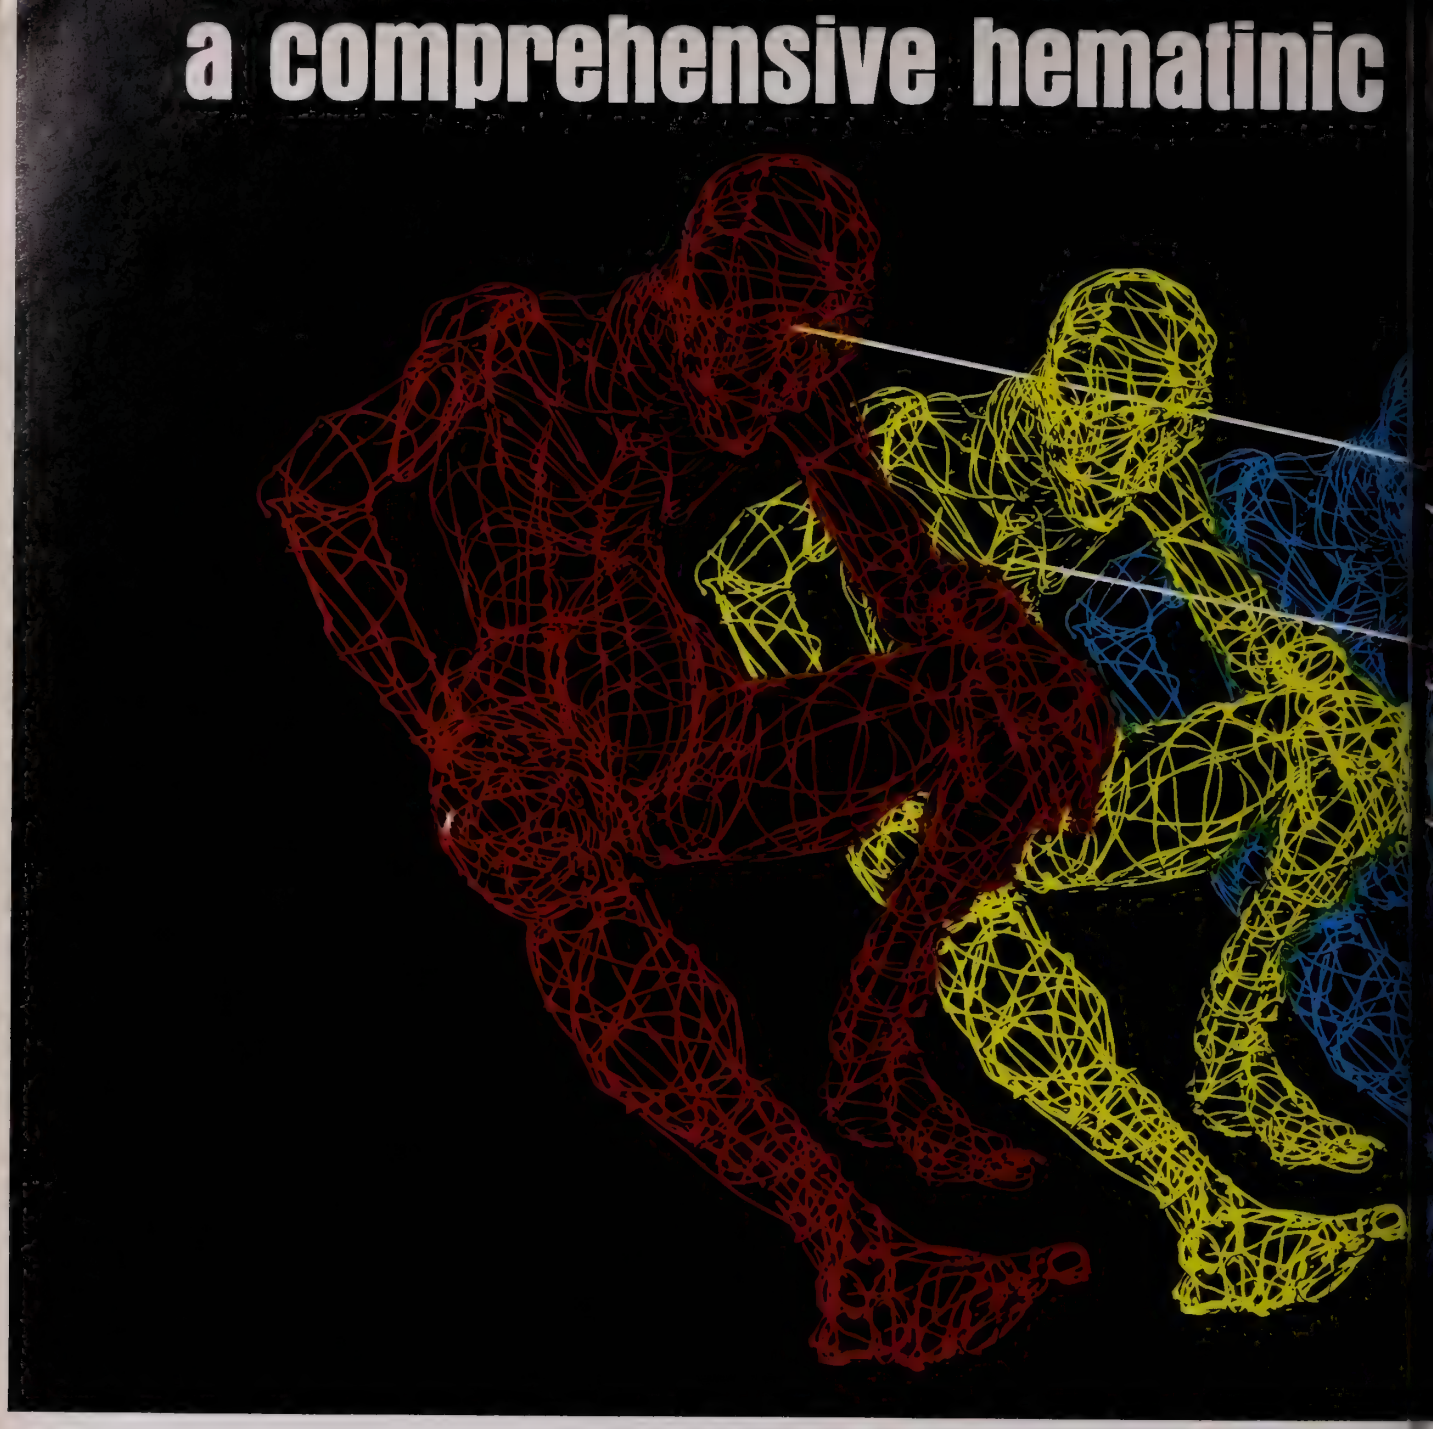
aluminum and magnesium hydroxides *plus* simethicone

"will it ease the pain?"

Mylanta helps relieve ulcer pain with the two most widely prescribed antacids: aluminum and magnesium hydroxides.

will it help "my gassy stomach"?

Mylanta *also* contains simethicone: for concomitant relief of G.I. gas distress.



"will this one taste O.K.?"

The *prolonged* acceptance of Mylanta was recently confirmed in 87.5% of 104 patients—after a total of 20,459 documented days of therapy.* *Danhof, I. E.: Report on file.

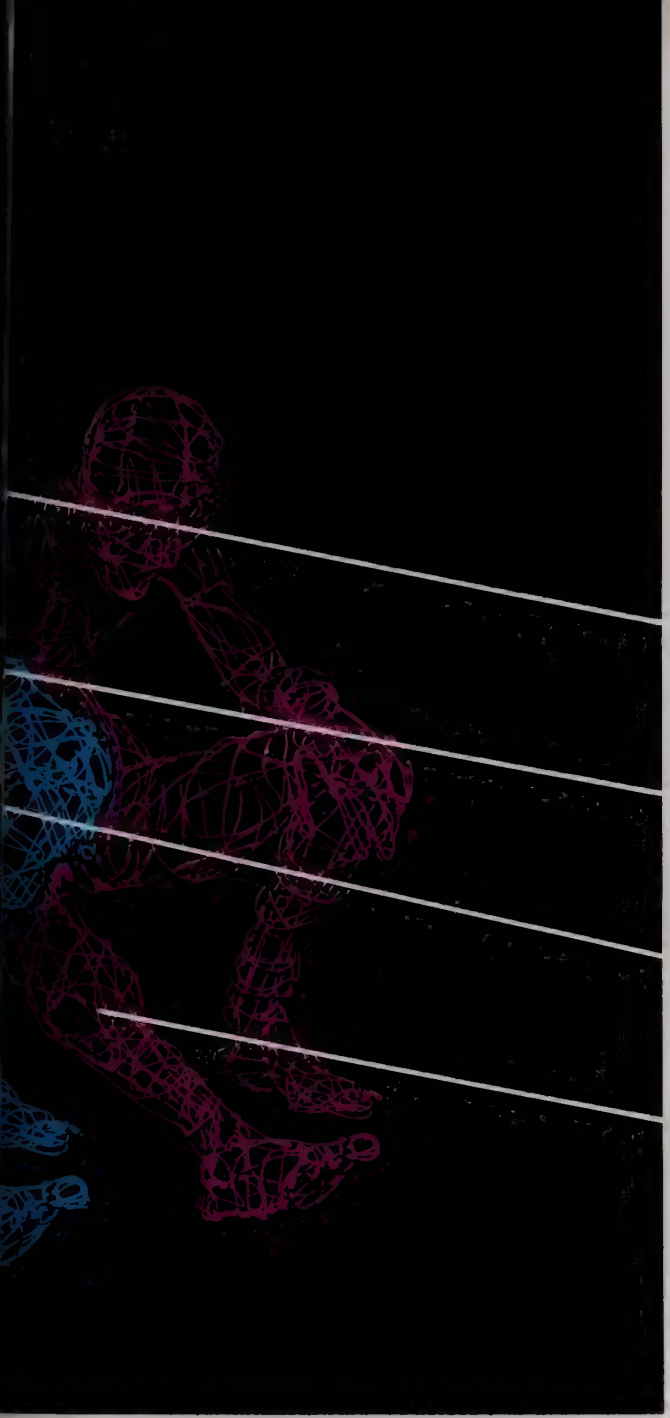
Composition: Each Mylanta chewable tablet or teaspoonful (5 ml.) contains: magnesium hydroxide, 200 mg.; aluminum hydroxide, dried gel, 200 mg.; simethicone, 20 mg. *Dosage:* One or two tablets (well chewed or allowed to dissolve in the mouth) or one or two teaspoonfuls to be taken between meals and at bedtime.

Stuart Division/Pasadena, Calif.
ATLAS CHEMICAL INDUSTRIES, INC.

a comprehensive hematinic

Description: Each Pulvule® contains—

Special Liver-Stomach Concentrate, Lilly (containing Intrinsic Factor)	150	mg.
Cobalamin Concentrate, N.F., equivalent to Cobalamin (The total vitamin B_{12} activity in the Special Liver-Stomach Concentrate, Lilly, and the Cobalamin Concentrate, N.F., is 15 micrograms.)	7.5	mcg.
Iron, Elemental (as Ferrous Fumarate)	110	mg.
Ascorbic Acid (Vitamin C)	75	mg.
Folic Acid	1	mg.



Indications: Trinsicon® (hematinic concentrate with intrinsic factor, Lilly) is a multifactor preparation effective in the treatment of anemias that respond to oral hematinics, including pernicious anemia and other megaloblastic anemias and also iron-deficiency anemia.

Contraindications: Hemochromatosis and hemosiderosis.

Precautions: Anemia is a manifestation that requires appropriat investigation to determine its cause or causes.

In pernicious anemia, the use of folic acid without adequat vitamin B_{12} therapy may result in hematologic remission but neu rological progression. Adequate doses of vitamin B_{12} (parentera or oral with potent intrinsic factor as in Trinsicon® [hematini concentrate with intrinsic factor, Lilly]) usually prevent, halt, c improve the neurological changes.

As with all preparations containing intrinsic factor, resistanc may develop in some cases of pernicious anemia to the potentia tion of absorption of physiological doses of vitamin B_{12}. If resis ance occurs, parenteral therapy, or oral therapy with so-calle massive doses of vitamin B_{12}, may be necessary. No single reg men fits all cases, and the status of the patient observed i follow-up is the final criterion for adequacy of therapy. Periodi

You can treat combined deficiencies with

Trinsicon®

—the multifactor hematinic

Vitamin B_{12} plus intrinsic factor (15 mcg. B_{12} activity)—helps provide adequate levels of this important vitamin.

Folic acid (1 mg.)—treats nutritional macrocytic anemias and/or malabsorption syndromes.

Ascorbic acid (75 mg.)—augments the conversion of folic acid to its active form and helps iron absorption.

Iron (110 mg.)—treats hypochromic anemia.

clinical and laboratory studies are considered essential and are recommended.

Adverse Reactions: In rare instances, iron in therapeutic doses produces gastro-intestinal reactions, such as diarrhea or constipation. Reducing the dose and administering it with meals will minimize these effects.

In extremely rare instances, skin rash suggesting allergy has followed oral administration of liver-stomach material. Instances of apparent allergic sensitization have also been reported after oral administration of folic acid.

Dosage: One Pulvule twice a day. (Two Pulvules daily produce a standard response in the average uncomplicated case of pernicious anemia.)

How Supplied: Pulvules Trinsicon® (hematinic concentrate with intrinsic factor, Lilly), in bottles of 60 and 500. [032568]

Additional information available to physicians upon request.

Eli Lilly and Company, Indianapolis, Indiana 46206.

"The inconvenience of a cold"

For a cold, NTz® Nasal Spray provides rapid relief of nasal symptoms. Relief starts with the first spray which opens the inferior part of the common meatus. A second spray, a few minutes later, will shrink the turbinates to help provide sinus drainage and ventilation. Dosage may be repeated every three or four hours as needed, for temporary relief of symptoms. NTz is well tolerated but overdosage should be avoided.

As a sinusitis deterrent, NTz Nasal Spray can be used to keep the nasal passages open during a cold to help prevent development of acute sinusitis—or to help prevent the acute condition from becoming chronic.

Supplied: NTz Nasal Spray, plastic squeeze bottles of 20 ml.; NTz Nasal Solution, bottles of 30 ml. (1 fl. oz.) with dropper.

NTz is more than a simple vasoconstrictor. It contains

Neo-Synephrine® (brand of phenylephrine) HCl 0.5 per cent, the major component, virtually synonymous with fast, efficient but gentle nasal vasoconstriction.

Thenfadil® (brand of thenyldiamine) HCl 0.1 per cent, topical antihistamine for reduction of rhinorrhea, sneezing or itching. It combats the allergic reactions that may occur in colds or sinusitis.

Zephiran® (brand of benzalkonium, as chloride, refined) 1:5000, antiseptic preservative and wetting agent to promote penetration and spread of the formula.

Winthrop Laboratories, New York, N.Y. 10016 Winthrop

Studies on the Circulation of Dogs

Following the Injection of Contrast X-ray Media*

N. HAHN, M.D.*
R. FELIX, M.D.*
N. DRAZNIN, M.D.*
Bonn, West Germany

A SERIES OF studies on human blood circulation after the peripheral injection of contrast X-ray media[9] revealed obvious changes of the blood pressure, the stroke volume, and the minute volume of the cardiac output.

In continuation we now report about studies done on anesthetized dogs. Pressures were determined in the aorta, in the pulmonary artery, and in the left atrium. Heart rate was recorded after the injection of 76% Urografin† and Urovison‡ into the right atrium in the same manner as in the selective dextrocardiography. Assuming that this type of injection produces a higher concentration of dye in the heart than when given peripherally, more obvious reactions should be expected.

Technique

We evaluated the electronically determined median pressure values§ and the heart frequencies as recorded by the electrocardiographs‖ on seven mongrel dogs, 18 to 25 kg. The dogs were sedated with Combelen+ subcutaneous, 1 mg/kg bodyweight, and after 20-30 minutes, 35 mg/kg Nembutal¶ intravenously.

Pressure in Aorta and Pulmonary Artery

Through an incision in the groin a catheter was inserted into the femoral artery to measure the pressure in the aorta, and another

catheter was passed through the femoral vein for the injection of dye into the right atrium. A catheter was then inserted through the right external jugular vein into the pulmonary artery for the purpose of determining the pressure. Thereafter a thoracotomy was performed and a catheter inserted through the left auricle into the left atrium. In order to prevent the lodging of the tip of the catheter against an atrial wall the catheter was fixated in the wall of the thorax. The correct position of the catheters was checked by radioscopy.

All values were recorded two to three minutes before and continuously for 10 minutes following the injection* of the dye into the right atrium. Normal saline or Ringer's solution was used in the control series.

Rebreathing

Some of the experiments were done in combination with unilateral rebreathing, in the same way as in certain pulmonary function studies[3]. After introduction of a Carlens-double lumen intratracheal tube we connected one tube with a five-liter-sized bag, in which one lung was rebreathing. This was done to check if there was a correlation between the increased pulmonary circulatory load and the possible qualitative or quantitative reactions of the general circulation in response to the injection of dyes. The timing of the dye injections and of the normal breathing and unilateral rebreathing was done in varied sequences.

Results

Because there were no differences found when the dyes or the Ringer's solution were injected under normal or unilateral breathing, the values obtained were treated in the same way. We took measurements at five, 15, 30, and 45 seconds after the start of the injections and thereafter every minute from one to 10 minutes. After the injection of normal saline or Ringer's solution the checking was done for five minutes because the values returned to normal in that time. In retrospect it appears that later measuring of the pressures in the pulmonary artery could have been of value.

*Elema-Schoenander AB, Stockholm. High-power injection syringe. Pressure of 1 atm/3 equals 14.69 lbs./square inch.

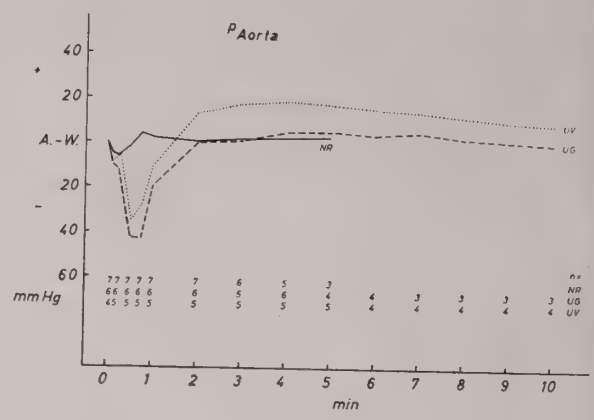

Figure 1.

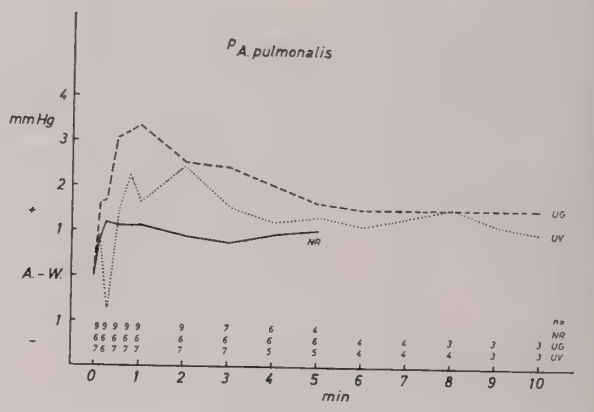

Figure 2.

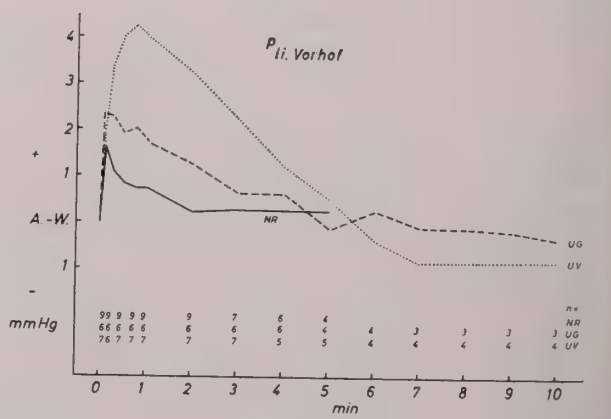

Figure 3.

Pressure Differences

Illustrations one to five show the measured values of the pressures in the aortic arteries, in the pulmonary arteries and in the left atria (Figures 1, 2 and 3). In addition, the pressure differences between the pulmonary arteries and the left atria and the heart rates are shown (Figure 4). All measured values were computed in relation to the starting values, not the absolute values, since there is less straying. This is particularly helpful when we are measuring the pulmonary artery and left atrium pressures, since the absolute values cannot be measured exactly the same way from one animal to the next because of technical difficulties. On one occasion we also checked the pressure in the caval vein. During the injection the pressure went up about 3 to 5 mm Hg, but thereafter no further changes were observed. Therefore further measurements were not taken.

*See Test Your Word Score Page 1583.

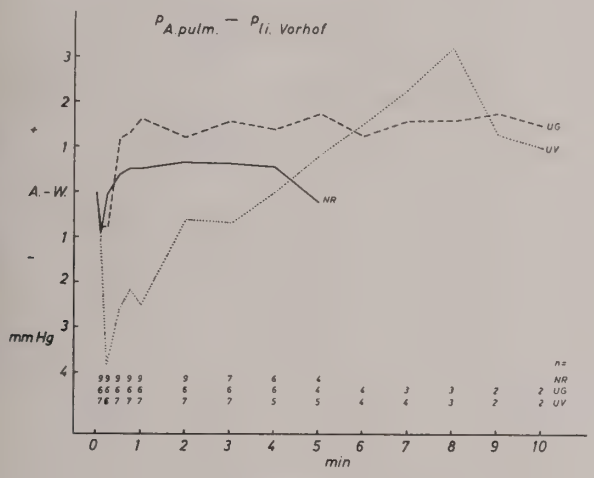

Figure 4.

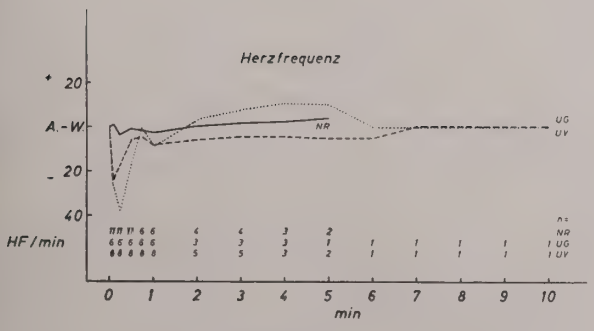

Figure 5.

Mean Values

Table 1 shows the mean values and the observed straying. For clearness we have not included the straying into the curves of the illustrations. Significant differences are reported in Table 2 with corresponding error possibility "p." Because of technical difficulties with the heart rate integrator we were unable to follow the injection of the one dye for the full 10 minutes, the other for only five minutes (Figure 5). The measured values are included in this illustration, but not in Table 1, since the statistical evaluation of the straying is not available.

Discussion

Contrary to the almost absent changes in the pressure of the aorta and the heart rate after injection of saline or Ringer's solution there are marked changes after the injection of Urografin and Urovison. After injection of these, a considerable drop in the aortic pressure and an increase of the pressure in the pulmonary artery and the left atrium occur, combined with a decreased heart rate.

According to these findings there were no changes caused by the sudden increase in volume (40 ml) in the right atrium after injection of normal saline or Ringer's solution; consequently it seems reasonable to presume that the reaction is not started by the volume but by the chemical constitution of the dye. Possibly a slight acidity may be of importance since the pH of Urografin is 7.15 and that of Urovison is 6.38.

Viscosity

The higher viscosity of the dyes has been said to have an influence on the circulation.[5] But the absolute viscosity of blood in vivo is 2.70 centipoise*.[11] The viscosity of Urografin 76% at 37° C is about 8.50 centipoise and that of Urovison about 3.30 centipoise. Urografin injection could therefore show some influence on the circulation, but probably not Urovison. Because the reactions after Urovison are occasionally more pronounced than after Urografin, an influence of the viscosity does not appear to be likely. Possibly the higher acidity may be the reason for the stronger

effects of Urovison.

Bezold-Jarisch Reflex

One may think about the possible appearance of a Bezold-Jarisch-reflex,[2,7,8] caused by reaction of chemical receptors in the left ventricle. In favor of this is the earlier onset of the reaction which occurs two to three seconds after the injection. The circulation time in the cat from the right atrium to the aortic bow is about three to four seconds.[8] Assuming a similar situation in the dog the reaction could be started in the left ventricle, but surgical section of the bilateral vagus nerves at the neck did not change the circulatory reaction of the dye injections; therefore our previously expressed opinion[9] about the presence of a Bezold-Jarisch reflex does not seem to be substantiated. Obviously the circulatory reaction originates locally by direct contact of the dye with the sinus node and the myocardium so that it might appear like a Bezold-Jarisch reflex.

Hypotonic Phase

After one to two minutes the depressed pressure and frequency values return to the starting point and thereafter keep rising. However, after 10 minutes the values are back at the pre-injection levels. This phenomenon might be explained by a centrally originating counter-reaction or by a direct central irritation.

The changes of the aortic pressure correspond with the findings of other examiners[1,4,10,12] and with our own findings in men.[9] We noted then a slight increase of the blood pressure two minutes after injection of Uro-

grafin, slowly decreasing to the tenth minute. Since we then checked the blood pressure with the method of Riva Rocci, we might possibly not have been able to find the drop in blood pressure during the first minute. Probably the observed time difference in the course of the reaction could be caused by the injection in a peripheral arm vein in human experiments. Also the amount of the dye injected into men was only 20 ml instead of 40 ml as used in the dogs; therefore a lesser dye concentration was present in the heart. This might also explain the less pronounced first phase, which in turn produced an earlier start of the second phase with an increased aortic pressure.

In the literature[6] two hypotonic phases are described in the aortic pressure after injection of a diazotrate in the carotid artery. We found that this phenomenon occurred only slightly and after a much shorter time than the 20 and 25 seconds described in the literature. We noted the first hypotonic phase after five seconds, the second after about 30 seconds. As this was seen only occasionally, it changes the median values in Figure 1 only slightly. The difference is probably caused by the varied sites of the injection: the contrast medium injected into the carotid artery reached the brain much earlier and in greater concentration than the dye injected into the right atrium.

The heart rate in dogs and men was influenced by the injection in the same way. The decrease in the aortic pressure and the slowing of the heart rate produce a slight stasis in the pulmonary circulation, as shown by the slight increase of the pressure in the pulmonary artery and the left atrium. While the changes in the aortic pressures are similar with the injection of Urografin and Urovison, they differ in the pulmonary artery and the left atrium. In the pulmonary artery there is a pressure increase of about 3 mm Hg one minute after the injection of Urografin. After injection of Urovison a pressure drop of about 0.75 mm Hg was noted after 15 seconds, followed later in the first or second minute by an increase of 2 to 2.5 mm Hg above the starting value. The pressure in the left atrium increases immediately after both dyes, but more with Urovison than with Urografin. After Urovison the pressure increases by 4 mm Hg maximal after one minute; after Urografin 2.5 mm Hg maximal after 15 seconds.

Hypertonic Phase

Computing the difference of the pressures between the pulmonary artery and the left atrium one notes an increase following a slight temporary decrease after 10 to 15 seconds, which does not subside within 10 minutes. The increase after Urovison starts after four minutes; the increase after Urografin after 20 seconds.

These differences between the two dyes and between the dyes and the saline solutions are not statistically valid because of the large stray deviations. But it is possible that the variations are caused by the different content of sodium and by the pH values.

The increase in the pressure differences between pulmonary artery and left atrium could be caused by an increase of the vascular resistance in the pulmonary circulation; but since we do not have cardiac output values, we cannot prove it. One would think, however, that the cardiac output probably drops with slowing of the heart rate. Decreased cardiac output in combination with increased pressure difference between pulmonary artery and left atrium would favor increased resistance of the pulmonary bed.

We have nothing to say about the resistance in the body circulation. The decrease in the difference of pressure between aorta and vena cava parallels the decrease of the heart rate, which probably causes a decrease of the cardiac output. But since we did not have the equipment to measure it, we cannot make any positive statements.

There are reports in the literature[6] about a decrease in the arterial resistance in an extremity after injection of a Diazotrate into the femoral artery. The cerebral arteries, on the other hand, contract. Therefore an increase in the resistance of the pulmonary circulation does not seem to be impossible. Such a phenomenon could be explained by multiple sites of reaction of the injected dyes: namely the heart, the blood vessels, and the cerebral centers of the vasoregulation.

There are reports about studies of the action of Urografin on the brain.[5] We cannot exclude the possibility that the changes in the pulmonary circulation are caused by central

action, but the primary hypotonic and bradycardiac phase is not caused centrally.

During the present studies we encountered the following complications: one dog died immediately after the injection of normal saline, and another dog developed an absolute arrhythmia due to atrial fibrillation.

This did not change spontaneously, however, but converted to sinus rhythm after injection of the contrast medium. In addition we noted two other occurrences of ventricular fibrillation after the dye injections, but they lasted only about 20 to 30 seconds and disappeared spontaneously. These difficulties were probably caused by irritation of the heart by the three indwelling catheters.

In the case of the dog that died a possible sensitivity of the sinus node to stretching may have been instrumental. The saline injection was the first injection given this dog. The atrial fibrillation could have been similarly caused. The ventricular fibrillation due to an irritation of the ventricular pathways is probably chemically caused.

Translated by: Heinrich H. Dierker, M.D.

Since all solutions were warmed to 37° before the injections no temperature effects could be expected.

Summary

Seven anesthetized dogs (Combelen-nembutal) were injected with 76% Urografin and Urovison through a catheter into the right atrium. The blood pressures in the aorta, the pulmonary artery and the left atrium in addition to the heart rate were measured continuously and simultaneously. The reactions caused by the two different contrast media were quite similar, but different findings were noticed in the left intra-atrial pressures and in the pressure differences between the pulmonary artery and the left atrium. For comparison, injections of normal saline and Ringer's solutions were given. There were significant differences in the action between the saline and the contrast media at different times. The reactions are probably caused by direct action on the sinus node and the myocardium, followed by action of the injected dyes at the cerebral centers.

Abdominal Syndrome

This term is used to designate the abdominal manifestations (pain and cramps) that may accompany an acute or subacute rheumatic process in childhood. The syndrome should be differentiated from acute mesenteric lymphadenitis that accompanies or follows acute sore throat. The presence of C-reactive protein, an elevated sedimentation rate, and antistreptolysin-O titer (over 317 units) strongly suggest rheumatic fever.

Temperance is the control of all the functions of our bodies. The man who refuses liquor, goes in for apple pie and develops a paunch is no ethical leader for me.—John Erskine

Finally...a salicylate superior to aspirin?

Not at all, Doctor...but

magan®

(magnesium salicylate, W-T)

should be considered for your arthritic and rheumatic patients who cannot tolerate aspirin.

Surveys * made in 1966 and 1967 among private practice physicians showed an incidence of intolerance to aspirin ranging from 3-85%. The majority of physicians surveyed reported an intolerance in 10-30% of their patients.

How does this compare with your experience?

*by two independent national research organizations

SUBSIDIARY OF **ROHM AND HAAS COMPANY**

10-30

Don't use Magan on all your patients–

consider Magan for those patients who cannot take aspirin because of gastric discomfort

Private Practice Physicians tried Magan on almost 700 patients whom they judged intolerant to aspirin and other salicylates.

The majority of these patients could take Magan and obtain the benefit of salicylate therapy.

magan® **an alternate salicylate**

(magnesium salicylate, W-T)

May be tolerated by some persons intolerant to aspirin by reason of gastrointestinal irritation.

Magan is a new salicylate product from Warren-Teed.

A single chemical entity . . . no coating, no buffering, sodium free and non-acetylated.

Composition: Each orange colored tablet contains 5 grains (approx. 325 mg) of magnesium salicylate.
Dosage: 1 or 2 tablets every 4 hours with a full glass of water.

*"Now that your acne is clearing up nicely,
it might be a good idea if you started losing some weight."*

Get them while they're easily reversible.

Obesity doesn't happen suddenly. This insidious process has its beginning—and the chances of reversing it are better—during the *first 10 to 15 pounds of weight gain.* When a new dietary pattern must be established, consider the adjunctive use of BAMADEX SEQUELS. Combining the proven *anorexigenic* action of d-amphetamine with the *tranquilizing* effect of meprobamate, BAMADEX SEQUELS controls appetite throughout the day, usually with a single capsule daily.

Contraindications: Dextro-amphetamine sulfate: In hyperexcitability and in agitated prepsychotic states. Previous allergic or idiosyncratic reactions to meprobamate.
Precautions: Use with caution in patients hypersensitive to sympathomimetic compounds, who have coronary or cardiovascular disease, or are severely hypertensive.

Dextro-amphetamine sulfate: Excessive use by unstable individuals may result in psychological dependence.

Meprobamate: Careful supervision of dose and amounts prescribed is advised, especially for patients with known propensity for taking excessive quantities of drugs. Excessive and prolonged use in susceptible persons, e.g. alcoholics, former addicts, and other severe psychoneurotics, has been reported to result in dependence on the drug. Where excessive dosage has continued for weeks or months, reduce dosage gradually. Sudden withdrawal may precipitate recurrence of preexisting symptoms such as anxiety, anorexia, or insomnia; or withdrawal reactions such as vomiting, ataxia, tremors, muscle twitching and, rarely, epileptiform seizures. Should meprobamate cause drowsiness or visual disturbances, reduce dosage and avoid operation of motor vehicles, machinery or other activity requiring alertness. Effects of excessive alcohol consumption may be increased by meprobamate. Appropriate caution is recommended with patients prone to excessive drinking. In patients prone to both petit and grand mal epilepsy meprobamate may precipitate grand mal attacks. Prescribe cautiously and in small quantities to patients with suicidal tendencies.
Side Effects: Overstimulation of the central nervous system, jitteriness and insomnia or drowsiness. Dextro-amphetamine sulfate: Insomnia, excitability, and increased motor activity are common and ordinarily mild side effects. Confusion, anxiety, aggressiveness, increased libido, and hallucinations have also been observed, especially in mentally ill patients. Rebound fatigue and depression may follow central stimulation. Other effects may include dry mouth, anorexia, nausea, vomiting, diarrhea, and increased cardiovascular reactivity.

Meprobamate: Drowsiness may occur and can be associated with ataxia; the symptom can usually be controlled by decreasing the dose, or by concomitant administration of central stimulants. Allergic or idiosyncratic reactions: maculopapular rash, acute nonthrombocytopenic purpura with petechiae, ecchymoses, peripheral edema and fever, transient leukopenia. A case of fatal bullous dermatitis, following administration of meprobamate and prednisolone, has been reported. Hypersensitivity has produced fever, fainting spells, angioneurotic edema, bronchial spasms, hypotensive crises (1 fatal case), anuria, stomatitis, proctitis (1 case), anaphylaxis, agranulocytosis and thrombocytopenic purpura, and a fatal instance of aplastic anemia, but only when other drugs known to elicit these conditions were given concomitantly. Fast EEG activity, usually after excessive dosage. Impairment of visual accommodation. Massive overdosage may produce drowsiness, lethargy, stupor, ataxia, coma, shock, vasomotor and respiratory collapse.

Sources of Sinus Headache

Sinus headache is often a reflection of congestion in the nasal mucosa. The pain that results in the various regions of the head may help in determining the particular structure(s) responsible. The proved formula of Sinutab which provides triple action — analgesic, decongestant and antihistaminic — is specifically designed for the symptomatic relief of sinus headache and nasal congestion.

INDICATIONS: Sinutab is indicated for the symptomatic relief of headache, facial pain, malaise, fever, nasal and sinus congestion often associated with acute and chronic sinusitis, allergic rhinitis, vasomotor rhinitis, influenza, and the common cold.

ADVERSE REACTIONS: Epigastric distress, drowsiness, dizziness, insomnia and nervousness.

PRECAUTIONS: Instruct patients not to drive or operate machinery if drowsiness occurs. Use with caution in patients with thyroid disease, heart disease, hypertension, diabetes or kidney disease. Excessive dosage or prolonged use may cause kidney damage.

DOSAGE: Adults — 2 tablets every 4 hours.
Children (6-12 years) — ½ the adult dose.

Each tablet contains 150 mg. acetaminophen, 150 mg. phenacetin, 25 mg. phenylpropanolamine HCl, and 22 mg. phenyltoloxamine citrate.

Source of Symptomatic Relief

Sinutab® | 2 tabs. q.4h.

MORRIS PLAINS, N.J.

Review

Causation as It Relates to Cancer Theory*

As evidence on the causes and nature of cancer rapidly increases, confusion seems to magnify rather than diminish. There are primarily two camps of cancer theorists: a genetic group that maintains that cancer is caused by a genotypic change, and a biochemical group that maintains that cancer is caused by a metabolic change. Much of the debate is due not to conflicting evidence but to failure to determine what is meant by "cause."

Etiology

So far as cancer is concerned, it is possible to distinguish four levels of causation:

1. A primary level which is the level of first cause (initiating cause). To say that something is the cause of cancer at this level means that it initiates the process.
2. A secondary level which relates to neoplasm continuity. To say that something is the cause of cancer at this level means that it is responsible for continuation of the process.
3. A tertiary level which relates to neoplastic properties. To say that something is the cause of cancer at this level means that it accounts for the tumor properties.
4. A quaternary level which relates to host response. To say that something is the cause of cancer at this level means that it allows the survival of the tumor (e.g., immune tolerance).

It is obvious that these levels of causation are not independent, but that each preceding level can be said to initiate the following level. Thus radiation acts upon the genotype to produce a continuing genotypic change (cancer state) which in its turn is responsible for tumor properties which in their turn may be partly responsible for failure of the host to eliminate tumor cells.

It is principally with the first level of causation that persons are concerned when they speak of "cause," even if they are at one and the same time confusing it with another level. It is probably readily apparent that the first and the third levels are most often confused. Because the first level is of primary concern, the rest of this paper will discuss causes of cancer at this level, looking at both the genetic and the metabolic viewpoints.

The Genetic Theory

The Chromatin

There is dramatic evidence that change in genotype is related to the development of cancer. The physical counterpart of the construct genotype, the chromatin, is increased in cancer cells, replicates more frequently, and is more darkly staining. The chromosomes are often abnormal, with deviation from normal number and changes in structure, including inversions, deletions, translocations, and ring forms. These changes in turn result in abnormal mitoses and are themselves the cause of abnormal mitoses. The multiple mitotic spindles of cancer cells are almost pathognomonic of the disease.[1]

Totipotential Cell

Additional support for the genetic theory comes from studies on the totipotentiality of germ cells and early cleavage cells demon-

*Paper supported in part by Grant CH05190 to Y. Maruyama, M.D., National Cancer Institute, National Institute of Health.

strated for amphibians and other animals, including man.[2] It is possible that cancer is one genotypic expression of a totipotential cell.[3]

But most important, cancer is transmissible from mother cell to daughter cell, and so probably involves the mechanism of genetic transmission and the genotype.[4]

While the evidence on a genetic mechanism for cancer allows a number of interpretations, it is possible to draw some conclusions that are more probable than others. Thus, while genetic change cannot be said to be the initiating cause of cancer, it is a necessary change reflected in the fact that cancer is somatically transmissible. Both genotypic change and the resulting increased rate of cell division seen in some cancers increase the probability of chromosome abnormalities.

The Metabolic Theory

Lactic Acid

As with the genetic theory of cancer, there is evidence to support the metabolic theory. Cancer cells exhibit a high rate of lactate formation, even under aerobic conditions[5]; related to this is the fact that they also exhibit a decreased uptake of oxygen in the presence of all essential metabolites. There is evidence to suggest that the Krebs cycle is only partially operative in tumor cells.[6-8] The formation of lactic acid seems to take precedence over everything else.[9]

Enzymes

As further confirmation of the metabolic theory, cancer cells have been found to possess a high concentration of adenosine triphosphate hydrolytic enzymes,[1] to incorporate a greater percentage of total amino acids into nuclear proteins, and in general to have fewer special components such as enzymes.[10-13]

In considering the possibility of a metabolic cause of cancer, the following points come to mind:

1. If metabolic changes initiate the process of cancer, then they probably do so by acting on the genotype.
2. The broad metabolic changes mentioned above are probably secondary to genotypic change, because they are themselves transmissible.

Analysis

Figure 1 is an attempt to relate genotypic change to phenotypic change. It takes the form of a spiral, from which it becomes apparent that there are two groups of primary causes of cancer (in the sense of this paper):

1. Changes in the genotype which do not involve endogenous biochemical intervention, and
2. Changes produced by endogenous biochemical mediation.

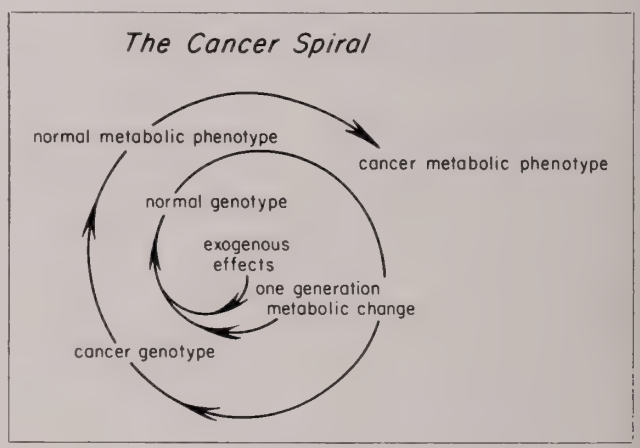

Figure 1

Both types of change will result in structural change in the cell genetic material. The structural change in turn can be considered more basically a chemical change.

A direct change in genotype seems readily possible, and there are a multitude of different effectors: radiation, drugs affecting nucleotide synthesis, incorporation of viral genes into the host genome. The change could likely involve the operon of Jacob and Monod (Figure 2). In this case, the operon might be called the cancer operon(s) and its impaired function would produce the expression of cancer. If there is a repressor associated with the operon, then: (1) the operon would produce the cancer state in the absence of this repressor, and (2) the repressor* would have to be its own template, because "one-generation biochemical effects"† produce transmissible change.

*The repressor probably acts through a substance whose manufacture it mediates.

†No mention is made of the duration of this change, which may be considerable in cells that do not have a rapid turnover, or any turnover.

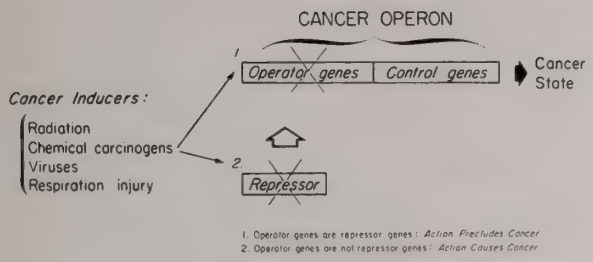

Figure 2

Now there is indeed a substance in the cell that is its own template, and that is deoxyribonucleic acid. It is therefore probable that the repressor is deoxyribonucleic acid. More directly, the repressor could be conceived as the operator gene itself. This reasoning is summarized in Figure 2.

It is therefore possible that cancer is due to a change in an operon, or more specifically in operator genes and, most specifically, in the structure of those genes, or in *base sequence*. Thus radiation, chromosomal deletion, translocation, incorporation of viral deoxyribonucleic acid, etc., alter base sequence in the operator genes and consequently destroy the inhibition of the operator, so that cancer becomes expressed.

The Special Case of the Warburg Theory

The Warburg theory is discussed separately here so that it can be related to the foregoing analysis. The Warburg theory is a metabolic theory of cancer that considers that respiration injury is the primary cause of the disease.[5] According to this theory, such injury results in the cancer cells' greater reliance on glycolysis as seen by a shift to aerobic fermentation. All the properties of cancer cells are considered to relate to this basic change. This is an extreme view only because it is posited as *the* cause of cancer. Indeed, it most certainly could be *a* cause of cancer.

If a cell requires a certain amount of energy to maintain its genetic coding, it follows that energy lack may damage that coding; it further follows that the cells that survive will exhibit a shift to aerobic fermentation as an alternative energy source making for survival. Thus Warburg's theory becomes consistent with the overall view set forth in this paper.*

*Warburg's theory as it relates to the cell grana has not been considered.

†Predoctoral Trainee, Division of Radiation Therapy, University of Minnesota Hospitals.

Summary

1. Cancer can be thought to have four different levels of causation.
2. Because cancer traits are transmissible from mother cell to daughter cell, cancer is likely to involve a change of genotype.
3. The change in genotype is mediated by a number of *primary causes* which are ultimately responsible for the presence, properties, and propagation of what is known as cancer. There is no primary cause of cancer, but there is likely only one secondary cause, or only one reason for neoplastic continuity, namely, genotypic change.
4. It is probable that changes in metabolism seen in cancer cells are due to changes in genotype. Any metabolic change that actually produced cancer would probably be masked or destroyed by the cancer metabolic phenotype. Precancer cells would be a more fruitful place to identify the existence of such changes, if such cells could be identified.

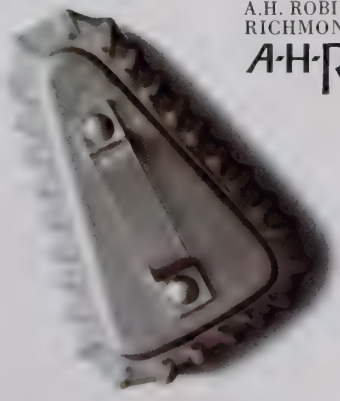
PUBLISHED AS A PUBLIC SERVICE IN COOPERATION WITH THE ADVERTISING COUNCIL

Help clear up that miserable stuffed-up feeling with Dimetapp. Each hard-working Extentab brings welcome relief from the stuffiness, drip and congestion of upper respiratory conditions for up to 10-12 hours. Yet, patients seldom experience drowsiness or overstimulation. The key to success is the Dimetapp formula: Dimetane (brompheniramine maleate)—along with phenylephrine and phenylpropanolamine, two time-tested decongestants. They get the job done... in a hurry.



Indications: Dimetapp is indicated for symptomatic relief of the allergic manifestations of respiratory illnesses, such as the common cold and bronchial asthma, seasonal allergies, sinusitis, rhinitis, conjunctivitis, and otitis.
Contraindications: Hypersensitivity to antihistamines. Not recommended for use during pregnancy.
Precautions: Until patient's response has been determined, he should be cautioned against engaging in operations requiring alertness. Administer with care to patients with cardiac or peripheral vascular diseases or hypertension.
Side Effects: Hypersensitivity reactions including skin rashes, urticaria, hypotension and thrombocytopenia, have been reported on rare occasions. Drowsiness, lassitude, nausea, giddiness, dryness of the mouth, mydriasis, increased irritability or excitement may be encountered.
Dosage: 1 Extentab morning and evening.
Supplied: Bottles of 100 and 500.

LOW-BACK PAIN

A CONSERVATIVE, FOUR-POINT PROGRAM

The low back pain that is most frequently seen in general practice is mechanical in nature, i.e., postural back pain, joint dysfunction and acute back strain.[1,2] For this type of discomfort, a conservative regimen is usually sufficient to relieve aches and pains, and to help keep the patient functioning. Components of this basic program include:

1 Bed "If the patient is in the pain-spasm-cycle...there is no alternative or substitute for absolute bed rest..."[3]

2 Board "Boards should be ordered under the mattress...these boards act by immobilizing the spine..."[4]

3 Heat "A very valuable method of applying heat at home is a prolonged hot bath..."[5]

4 Robaxin®-750 (methocarbamol, 750 mg. capsule-shaped tablets) A well-tolerated[6] skeletal muscle relaxant, methocarbamol helps relieve spasm "...without interfering with normal tone and movement."[7] And there is little likelihood of sedation.[6]

Indicated for relief of skeletal muscle spasm. **Contraindicated** in hypersensitive patients. **Side Effects** (lightheadedness, dizziness, drowsiness, nausea) may occur rarely, but usually disappear on reduced dosage. Hypersensitivity reactions develop infrequently. See product literature for further details. **Also available:** Robaxin® Tablets (methocarbamol, 500 mg.) Robaxin Injectable (methocarbamol, 1 Gm./10 cc.)

Abstracts, Briefs and Commentaries

THE COMPARATIVE APPRAISAL OF THE EXPLORATIVE METHODS OF GASTRIC SECRETION IN STOMACH DISEASES (ULCER, CANCER, GASTRITIS, NEUROSIS WITH DIGESTIVE DISTURBANCES)

The gastric secretion was followed up by a personal special record card, before and after alcohol, insulin and histamine. The studied parameters were: the volume of gastric secretion per hour (V. H.), the maximal acid output per hour (M. A. O.), the buffer potency (B. P.), the deficiency in acid per hour (D. A. H.), the ration between the basal and stimulated secretion, the acid/alkaline secretion ratio, and in some cases investigations of the electrolytes of the gastric juice.

The conclusions of the authors are the following:

1. Each gastric tubing, in order to draw conclusions, has to be repeated, because there are situations when the stomach can temporarily lose the property to secrete its usual quantity of HCl. Its secretory function can for different reasons be diminished or abolished for a shorter or longer period. It is imperative to repeat the tubing, especially when achlorhydria is found.

2. In gastritis, gastric ulcer and gastric cancer, the greatest and most constant value of acidity appears after the use of histamine.

3. After alcohol there are variations from day to day, especially in neurosis with digestive disturbances and in duodenal ulcers. In patients with hyperalgesic forms of duodenal ulcer, there were higher values transfer after insulin than after histamine.

4. In some patients the V. H. transfer after histamine increased more than the ratio of HCl. The authors inquired whether this was due to hypersensitivity of the gastric mucosa to histamine.

CONDITION OF THE PANCREAS IN CIRRHOSIS OF THE LIVER

The function of the pancreas was examined in 181 patients suffering from cirrhosis of the liver. To evaluate the external pancreatic secretion, the activity of blood pancreatic enzymes (amylase and amylase curves, trypsin inhibitor and lipase) was studied, and intestinal absorption of fat and proteins was examined by means of radioactive isotopes. Morphological findings were considered in 18 cases (post-mortem examination).

Seventy patients displayed a disturbance of pancreatic function, those with portal and biliary cirrhosis in particular. Scanning of the pancreas (Z-Se-75-selenium-methionine) showed diminution of the absorbing capacity. A simultaneous lesion of the pancreas and intestinal wall was revealed in 18 patients with cirrhosis of the liver and ascites by means of the subsequent use of two radioactive substances (glycerin trioleate and oleic acid). Involvement of the intestine was confirmed by needle biopsy.

A close dependence was observed between the severity of the liver affection and the degree of abnormalities in the pancreatic function tests.

Fibrosis of the pancreatic tissue and the presence of atrophic and hypotrophic islets in it were encountered in cases with portal cirrhosis. In postnecrotic cirrhosis of the liver attended with hepatic coma, vascular disorders prevailed in the pancreas: congestive hyperaemia, stasis, and the presence of nonfibrinous thrombi. Destructive and necrotic foci were found in the hepatic and pancreatic tissue in the active phase of cirrhosis.

The possibilities of various diagnostic methods are discussed in the report.

PRIMARY SYPHILIS OF THE ANORECTAL REGION

Nowadays homosexual behaviour plays an important part in the transmission of syphilis; homosexual contacts seem to be responsible for about 25-50% of primary syphilis in males. The patient is likely to ascribe his anal symptoms to piles. Experience has also shown that the disease is unlikely to be correctly diagnosed in its primary stage. Because a venereal disease is seldom suspected in this area, the patients as a rule are not referred to a venereologist but to a surgeon interested in enterology. Ten cases of anorectal syphilis have been seen in our Department during the years 1958-1967. Excluding a female where the lesion looked like an early carcinoma of the rectum, the group consisted of nine single men, all admitting homosexual exposure. Anorectal syphilis has to be diagnosed early, as the local changes rapidly disappear and heal spontaneously within three to four weeks. Among the diseases to be considered in the differential diagnosis of this region are anal fissure, hemorrhoids and anal manifestations of Crohn's disease, basal and squamous cell carcinoma of the anal canal and even carcinoma of the rectum. It is probable that the comparative rarity of the cases is more a case of overlooking or misinterpreting the lesions, than a low frequency of luetic infections of the anorectal region. An improved awareness of the possibility of syphilis in this region will allow earlier diagnosis and treatment and prevent spreading of the disease.

CLINICAL AND HISTOLOGICAL FINDINGS OF ALCOHOLIC LIVER DAMAGE

The authors studied clinicopathologically 150 patients who had taken over 135 g of alcohol almost daily, and analyzed alcoholic hyaline with light and electronmicroscope according to Mallory's experimental report.

From the findings of biopsy examination, these cases were classified into several groups, such as hepatosis, hepatitis-type, fibrosis, precirrhotic type and cirrhosis. Variable necrosis was found in parenchyma and around portal fibrotic area; inflammatory cell infiltration in necrosis was ordinarily mild. In repeated biopsy examinations, liver cell changes were capable of returning to normal; however, necrotic changes turned to fibrosis and proceeded to pseudolobules, especially in patients who did not cease alcoholic ingestion.

We would like to emphasize necrotic process as a very important factor leading to pseudolobular formation.

Liver function tests, especially bromsulphthalein and ZST, were parallel to histological findings. The amount of alcohol ingested daily was somewhat correlated to the degree of histological findings; nutritious factor also seemed to contribute to the phenomena considerably. These alcoholics were mostly of low income.

Typical alcoholic hyaline was found in only two cases. Histological study of hyaline will be discussed according to Mallory's work.

NATURAL HISTORY OF RECTAL POLYP

In a seven-year study of 132 patients whose rectal polyps were left intact a total of 414 sigmoidoscopies were performed. The patients were examined periodically with both photography and cytologic examinations. The average age was 64 years. Of the 132 patients, 52 died without cancer of the colon or rectum. In five patients repeated follow-up examinations failed to detect the polyp. In 16 patients the original polypoid lesion showed malignant cytology and was removed because of suspected malignancy; these were true cancers. Two patients had suspicious cells on cytology and the polyp was removed through the proctoscope; on biopsy these polyps had only foci of malignant glands. In three patients the follow-up period was too short to be meaningful. Of the remaining 54 patients, four developed malignancy of the large bowel; these four were sigmoidoscoped on 23 occasions and had an average follow-up of 38.7 months, representing a total of 154 "polyp months." One of these cancers was a carcinoid and three appeared in areas other than the originally detected polyp. The remaining 50 patients had an average follow-up of 22.3 months, giving a total of 1,115 "polyp months." The appearance of benign rectal polyps did not change during the years of follow-up.

RESULTS OF MEDICAL THERAPY IN ULCERATIVE COLITIS

A review of a series of patients who were treated conservatively in the pre-steroid era revealed that complete symptomatic and proctoscopic remission took place in 7 percent in one month and reached 40 percent in six months. The remission rate in a group of patients recently treated with steroids was 13 percent in one month, reaching 47 percent in six months. The remission rate in a series of patients on sulfasalazine was similar to that observed with steroid therapy, ranging from 14 percent in one month to 40 percent in six months.

The relapse rate in patients who had achieved a remission without benefit of either steroids or sulfasalazine was 18 percent in one month, whereas the relapse rate after steroids was 37 percent in one month. At six months the incidence of relapse was 45 percent in symptomatically treated patients and 57 percent in the steroid group.

The effect of steroids in causing a more rapid remission in ulcerative colitis and the tendency to relapse when steroids are discontinued, are both in accord with the view that steroids act by inhibiting the inflammatory reaction in the bowel. Sulfasalazine also appears to act in a similar manner although somewhat more slowly.

Abstract of presentation made during Congressus Gastroenterologiae Internationalis, VIII, in Prague, 1968.

CLINICAL AND EPIDEMIOLOGICAL STUDIES ON CARCINOMA OF THE PANCREAS

Clinical observations of carcinoma of the pancreas were made in 1070 collected cases confirmed by histology, necropsy or laparotomy in Japan during the nine years from 1959 through 1967. In this series there were 703 males and 367 females. In 1030 of 1070 cases, symptomatology, histological classification, average survival period, surgical procedure, and prognosis were studied according to the site of lesion.

Secondly, previous dietary, smoking, drinking habits were surveyed in 475 cases of carcinoma of the pancreas among the collected cases, as well as hundreds of thousands healthy control-adults interviewed in 29 health center districts in Japan. The relative risk of carcinoma of the pancreas was calculated in both study and control groups. It was noted that the risk of this malignant disease was significantly higher in patients who were heavy smokers, had the habit of daily drinking alcoholic beverages, and also ate fewer green-yellow vegetables.

CLINICAL DIAGNOSIS OF CANCER OF BODY AND TAIL OF PANCREAS

On reviewing the clinical records of Memorial Hospital (New York City) from 1926 through 1965 there were 150 patients with histologically-proved carcinoma of the body or tail of the pancreas. The salvage from this neo-

plasm is low, largely due to the fact that the diagnosis is not made until the disease is far advanced. A review of the symptoms and findings in these 150 patients is presented to emphasize the difficulty of early diagnosis and, in so doing, to encourage the practitioner to suspect the diagnosis more frequently when confronted with a patient complaining of abdominal pain, bowel irregularities and insensible loss of weight.

EFFECT OF TREATMENT WITH THE ANTITUBERCULOUS DRUGS PYRAZINAMID AND ETHIONAMID ON THE LIVER

In 48 patients with pulmonary tuberculosis treated with pyrazinamid and/or ethionamid possible hepatotoxicity of these drugs was followed by means of a battery of liver tests and liver biopsies. In the majority of patients the liver tests and the histological examinations of the liver were performed both before commencement of treatment and after three to six months of treatment with the antituberculous drugs. Neither the liver tests nor the liver biopsies indicated any harmful effect of the treatment with pyrazinamid and ehionamid. Owing to a possible individual sensitivity regular examinations of the liver are still recommended during treatment with the antituberculous drugs.

GROWTH RETARDATION IN CHILDREN WITH INFLAMMATORY BOWEL DISEASE

Defining growth retardation as height below three standard deviations from normal, we have identified 25 children with growth retardation associated with inflammatory bowel disease. These 25, 16 male and nine female, represent 10% of the child population at the University of Chicago Hospitals. Fifteen (60%) had small intestinal disease (regional enteritis or ileocolitis) and 10 (40%) colonic disease (ulcerative colitis or granulomatous colitis). Nine had malabsorption. Though 23 patients received corticosteroids, there was retardation of growth in eight individuals (33%) prior to any form of therapy and in six (25%) preceding any gastrointestinal symptoms.

Two of four patients did not manifest a significant growth hormone elevation in response to insulin-induced hypoglycemia (assays on the remainder are in progress).

Other considerations include the vulnerable age range, extent and severity of disease, presence of other disorders (emotional, renal and hepatic) and the effectiveness of therapy directed to the intestinal disease (corticosteroids and intestinal resection) as well as to the growth problem (androgens).

Classified Advertisements

Classified advertising rates are twenty (20) cents a word; minimum monthly charge $5.00; key number, fifty (50) cents additional.

Replies to advertisements with key numbers should be mailed in care of Minnesota Medicine, 375 Jackson, St. Paul, Minn. 55101.

WANTED: GENERAL PRACTITIONERS, anesthesiologist, Urologist, Obstetrician, Orthopedist, & Pediatrician needed in growing community of 15,000. Service area 25,000. Present 83 bed general hospital. New 100+ bed automated hospital to be completed within 2 years. City has excellent industry, school system, and recreational activities. 45 minutes from Madison or Milwaukee. Future unusually promising. For more information contact: Administrator, Watertown Memorial Hospital, Watertown, Wis.

THREE MAN group in North West Wisconsin Resort, State Conservation and Retirement Area needs two more physicians adequately to serve their practice. Facilities offered are three-room physician suites, X-ray and lab under AMT technician, RN-only nursing personnel. New accredited thirty-two bed hospital and forty-six bed nursing home. Deer and duck hunting, fishing within five minutes of town. Internist most needed; generalists welcomed. Will meet any reasonable salary request. Partnership after one year. Write: MINNESOTA MEDICINE—365; 375 Jackson St., St. Paul 55101.

BENSON & ASSOCIATES: Business & Professional Collection Specialists. No charge if no collection made. Pho: 888-2242, 8601 Nicollet Ave., Bloomington, Minn.

THE WEST MEDICAL CLINIC has an opening for a General Practice Physician, on October 1, 1968. This is a five man group that conducts a practice near downtown St. Paul and also, has the Airport Medical Clinic at Wold Chamberlain Field, Twin City International Airport. Both clinics have full laboratory and X-ray services with technologists covering both fields.

The Airport Medical Clinic does industrial, occupational and Aviation medicine. FAA examinations are conducted at both clinics.

The clinic located near downtown St. Paul has a practice limited principally to internal medicine, pediatrics, as well as occupational and industrial medicine. There is only a limited practice of obstetrics and no surgery.

Salary is open and opportunity for partnership is available. Write: West Medical Clinic, 539 W. Seventh Street, St. Paul, Minnesota 55102. Phone: Area Code 612-227-9341.

WANTED: Physician for ward and/or clinic in accredited State Mental Hospital in fishing and hunting area of Minnesota. Should have interest though not necessarily experience in mental health and illness. Living quarters provided. Send vita with application. Not a retirement position. Older physician with good credentials acceptable. Write: MINNESOTA MEDICINE-414, 375 Jackson St., St. Paul 55101.

GENERAL SURGEON interested in some general practice to associate with a 2-man partnership in a rich agricultural community in southern Minnesota. Modern hospital and new clinic building. Hunting, 9-hole golf course, swimming pool. Salary open and full partnership as soon as desired. Write: MINNESOTA MEDICINE—405, 375 Jackson, St. Paul 55101.

WANTED General practitioner, to join two G.P.'s well established in north central Minnesota community 2200 pop., 65 miles from Twin Cities. Excellent office space with lab and X-ray, just opened new hospital all facilities. Assistantship or partnership. Considerable surgery and obstetrics. Hunting, fishing, golf club. Great opening for interested G.P. write MINNESOTA MEDICINE—381; 375 Jackson, St. Paul 55101.

INTERNIST AND GENERAL PRACTITIONER wanted to join a five-man clinic group in Minneapolis. Complete laboratory and X-ray with board roentgenologist. Excellent hospital staff associations. Salary arrangement to start with, early partnership. Write MINNESOTA MEDICINE—289; 375 Jackson, St. Paul, 55101.

PRACTICE FOR SALE: Well established general practice in South Minneapolis serving an excellent community, within easy reach of the finest hospitals in the State. Very reasonable, low overhead. Splendid opportunity for solo or partnership practice. Write: MINNESOTA MEDICINE—397, 375 Jackson St., St. Paul 55101.

JACK HEIMARK, Donald Freeman, Hobert Setzer, and John Eustermann would like to do more hunting, fishing, and traveling, and would appreciate sharing their time with additional Internists at the Mankato Clinic, Mankato, Minnesota. If you are Board Qualified or eligible and seeking a position, any of them would appreciate hearing from you.

FOR SALE: Busy general practice northern Minnesota. Ideal for 1 or 2 doctors. Clinic, 14 rooms with lab. and X-ray. Good community hospital. Fine home. Will introduce. Write: MINNESOTA MEDICINE—416, 375 Jackson, St. Paul 55101.

FOR SALE: (1) Kelley-Koeb 30 MA X-ray unit-table (tilting), fluoroscope, bucky plus all dark room equipment. (2) Portable X-ray unit with stand—for home (bedside) use. (3) 3 Unit sterilizer (gas operated)—water, instruments, dressings, etc. Phone or write Dr. A. J. Emond, Farmington, Minn. 55024. Tel. 463-8624.

DIRECTOR OF MEDICAL EDUCATION, full time —Methodist Hospital, St. Louis Park, Minnesota 55426. Contact Mr. Earl Dresser, Administrator or Dr. W. John Dawson, acting director of medical education.

WANTED: General practitioner to join two young general practitioners in well-established practice in suburban St. Paul. Excellent office space with lab, x-ray, and emergency room. Salary negotiable, with an association leading to early partnership opportunity. Write MINNESOTA MEDICINE 412, 375 Jackson St., St. Paul 55101.

FOR RENT: 14-room deluxe clinic in shopping center—Robbinsdale. 5 min. from Glenwood Hills and No. Memorial Hospitals—3 months rent free—will subdivide—36th Ave. No. and Noble—Noble Drug, JU 8-9449—Ben or Lou.

NINETEEN-MAN Wisconsin group located in college community of 40,000 with excellent hospital facilities is seeking additional associates in the following areas: (1) Internal Medicine, (2) Urology, (3) General Practice, and (4) Pediatrics. For further information please contact D. R. Griffith, M.D., Midelfort Clinic, Eau Claire, Wisconsin 54701.

ASSOCIATE urgently needed in busy general practice. Excellent clinic and hospital facilities. Salary open. Partnership after 1 year. Klefstad Clinic, Greenbush, Minn. Call collect: Lloyd H. Klefstad, M.D., Tele. 218—782-5275 or 4725.

GENERAL PRACTITIONER WANTED: To associate with Physician-Surgeon in Owatonna, a Southern Minnesota community, 25,000 population. Clinic building 3 years old, with five large treatment rooms, lab., x-ray, central supply, two doctors' offices, pharmacy, and business offices. Located next door to 85 bed City Hospital. Good opportunity for partnership. Contact: O. W. Roberts, M.D., 920 South Cedar Street, Owatonna, Minnesota. Phone 451-4630.

WANTED: G.P. in sunny Arizona. Rapidly expanding Student Health Service, with 23 generalists and specialists, needs you. 50-bed licensed hospital with large outpatient clinic. Many fringe benefits. Insurance, retirement, vacation benefits and regular hours with minimal night call. New salary schedule attractive as are living and climate. Arizona license by reciprocity. Contact Paul J. Matte, M.D., Director or William R. Perrin, M.D., Assistant Director, Student Health Service, University of Arizona, Tucson, Arizona 85721.

MAPLE LAKE, MINNESOTA. An active established general practice avaliable in town 40 miles northwest of Minneapolis, Minn. Good school system, active community, attractive lake country. Present physician retiring because of illness. Write S. J. Raetz, M.D., Maple Lake, Minn. 55358 or Call collect 963-3920.

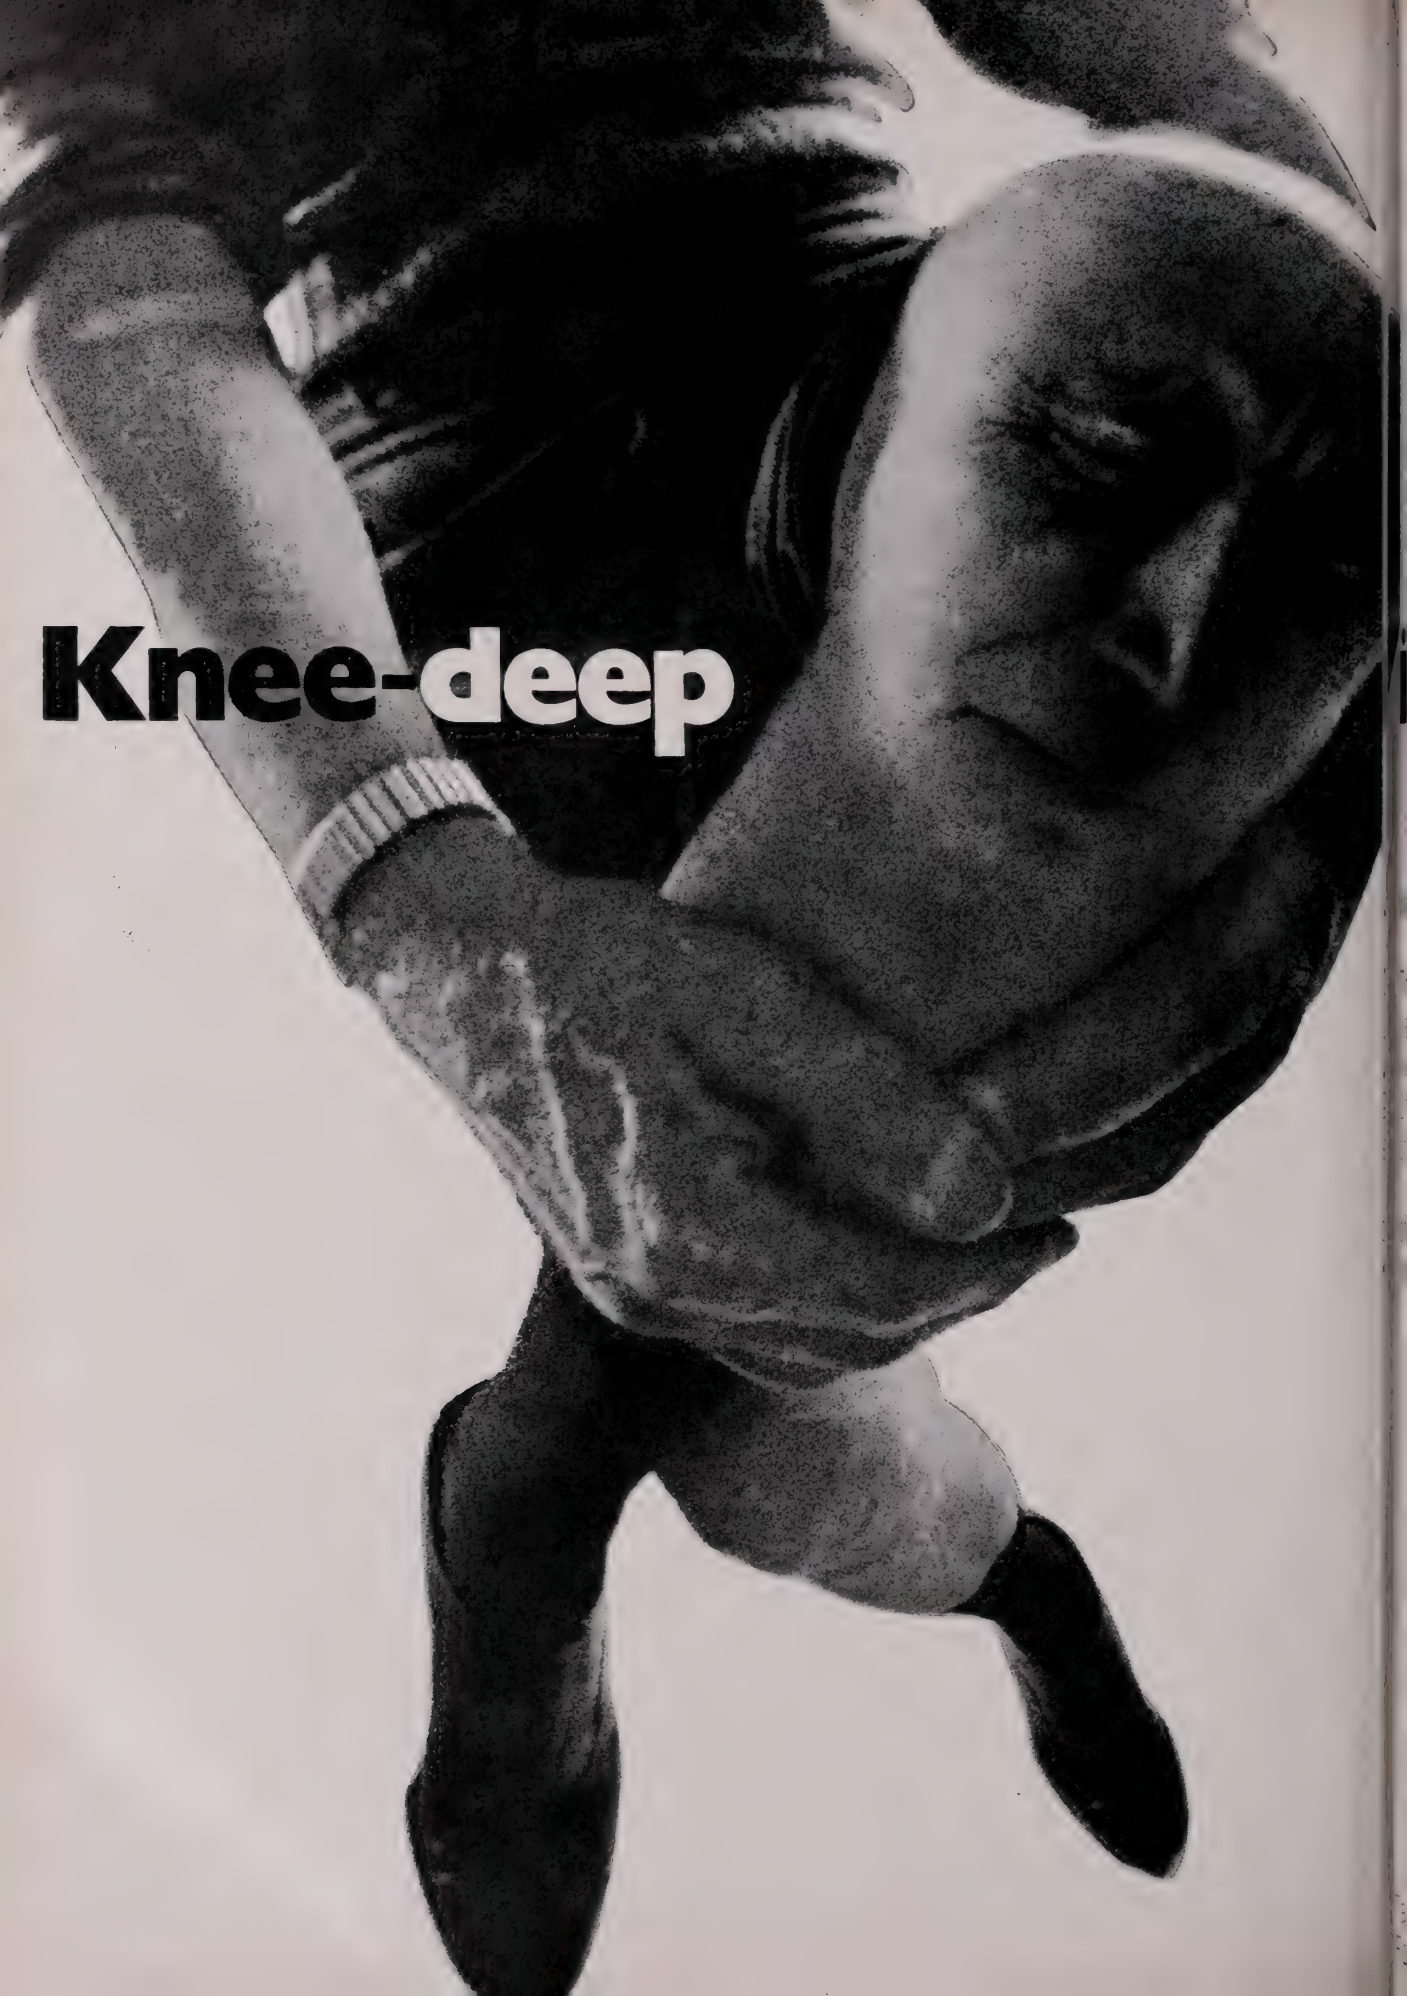
SURGEON; Board certified; FACS; desires part time surgical or industrial association—hours flexible. Write MINNESOTA MEDICINE 418, 375 Jackson, St. Paul 55101.

TWO MAN GROUP needs a third general practitioner in a fast-growing West St. Paul area. Begin with salary and assume early partnership. Contact N. W. Howe, M.D., or E. J. McEllistrem, M.D., 1246 Gorman, West St. Paul, Minn. 55118 Telephone: 224-8001.

WANTED: G.P. to join clinic serving population area of 12,000. City has new hospital, new clinic building, two nursing homes, new Jr-Sr high school, new swimming pool, rich farming area in Red River Valley. Fishing and hunting nearby; metropolitan city close by. Salary open and partnership if interested. Write or call Warren Clinic, Warren, Minnesota 742-6231, area code 218.

GENERAL PRACTITIONER wanted to join well-established practitioner. New clinic building—90 miles east of St. Paul—city of 14,000. Early partnership with full hospital facilities. Ideal location. L. W. Picotte, M.D.; Chippewa Falls, Wisconsin.

PSYCHIATRIST—board eligible, desires association with individual or group in Twin Cities area. Eight years experience in general and forensic psychiatry. Write MINNESOTA MEDICINE-413, 375 Jackson St., St. Paul 55101.



LONG LAKE needs doctor. Professional bldg. for sale or rent. Has waiting room with reception counter, two toilets, lab-darkroom, large X-ray room plus five other rooms. Picker 100-100 century now installed. Sublease area has large room and toilet, suitable for Dentist or other Professional with shared waiting room. All new modern interior. Wide open; no doctor in town. Jay R. Kallestad. A.C. 612-920-7687.

TWO PHYSICIANS NEEDED IMMEDIATELY—partner left September, 1968. Prefer either a general surgeon with some GP experience or GP with general surgery experience, and internist willing to do some general practice or GP. Industrial town of 3,500 economically unsurpassed in many aspects, located in NE Minnesota in Superior National Forest. Three large industries in town employ 2100 & I am only MD present. Practice consists of large private practice & treatment of industrial injuries. Large clinic with complete facilities including 500 ma xray with stereo, lab with Coleman spectrophotometer & attachments, audiogram room, Burdick EKG with all attachments, ER fully equipped, & all PT equip. Staff consists of five x-ray lab techs, RN & secretary. Good housing for rent or purchase with no down payment required. Unexcelled hunting-fishing-boating-camping-golfing. Equal vacation (6 wks) with rotating night & weekend call. Unexcelled school system & most churches represented. Should enjoy outdoor recreation to appreciate area. Fifteen minute drive to modern hospital & nursing home. High collection rate & very low overhead. Excellent liberal income including fringe benefits with full partnership eventually available. Write with all particulars or call after 6 p.m. All replies will be kept strictly confidential. T. C. Leach, M.D., Babbitt, Minn. 55706, (218) 827-6830.

The obvious is that which is never seen until someone expresses it simply.—Kahlil Gibran

There is nothing more beautiful in this world than a healthy wise old man.—Lin Yutang

Knee-deep

in osteoarthritic pain

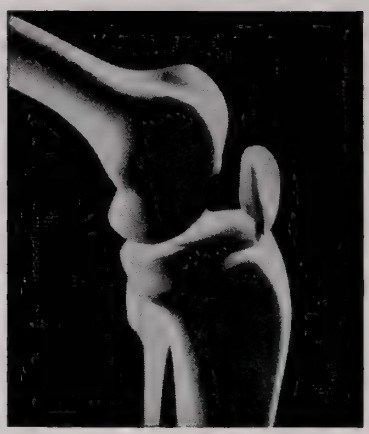
If aspirin doesn't help, move in with Tandearil.

The trial period is brief: 1 week. Try one tablet q.i.d. at first. Tandearil usually starts working within 3 to 4 days. When response occurs, as little as 1 or 2 tablets daily may hold back pain and stiffness, and increase joint motion.

On the next page is a summary of adverse reactions, contraindications, warning and precautions.

Tandearil.
It can help get his mind off his knee.

Please review full Prescribing Information carefully before prescribing.



For osteoarthritic knees, spines, shoulders, hips, etc.:

Tandearil®
oxyphenbutazone

Tandearil, oxyphenbutazone:
For brief summary see next page.

Geigy

TA-6006

Tandearil®
oxyphenbutazone

Contraindications: Edema; danger of cardiac decompensation; history or symptoms of peptic ulcer; renal, hepatic or cardiac damage; history of drug allergy; history of blood dyscrasia. The drug should not be given when the patient is senile or when other potent drugs are given concurrently.

Warning: This drug is an analog of phenylbutazone; sensitive patients may be cross-reactive. If coumarin-type anticoagulants are given simultaneously, watch for excessive increase in prothrombin time. Instances of severe bleeding have occurred. Persistent or severe dyspepsia may indicate peptic ulcer; perform upper gastrointestinal x-ray diagnostic tests if drug is continued. Pyrazole compounds may potentiate the pharmacologic action of sulfonylurea, sulfonamide-type agents and insulin. Carefully observe patients receiving such therapy. Use with caution in the first trimester of pregnancy, and in patients with thyroid disease.

Precautions: Before prescribing, carefully select patients, avoiding those responsive to routine measures as well as contraindicated patients. Obtain a detailed history and a complete physical and laboratory examination, including a blood count. The patients should not exceed recommended dosage, should be closely supervised and should be warned to discontinue the drug and report immediately if fever, sore throat, or mouth lesions (symptoms of blood dyscrasia), sudden weight gain (water retention), skin reactions, black or tarry stools or other evidence of intestinal hemorrhage occur. Make complete blood counts at weekly intervals during early therapy and at 2-week intervals thereafter. Discontinue the drug immediately and institute countermeasures if the white count changes significantly, granulocytes decrease, or immature forms appear. Use greater care in the elderly and in hypertensives.

Adverse Reactions: The more common are nausea and edema. Swelling of the ankles or face may be minimized by withholding dietary salt, reduction in dosage or use of diuretics. In elderly patients and in those with hypertension, the drug should be discontinued with the appearance of edema. The drug has been associated with peptic ulcer and may reactivate a latent peptic ulcer. The patient should be instructed to take doses immediately after meals or with milk to minimize gastric upset. Drug rash occasionally occurs. If it does, promptly discontinue the drug. Agranulocytosis, exfoliative dermatitis, Stevens-Johnson syndrome, Lyell's syndrome (toxic necrotizing epidermolysis), or a generalized allergic reaction similar to a serum sickness syndrome may occur and require permanent withdrawal of medication. Agranulocytosis can occur suddenly in spite of regular, repeated normal white counts. Stomatitis, salivary gland enlargement, vomiting, vertigo and languor may occur. Leukemia and leukemoid reactions have been reported. While not definitely attributable to the drug, a causal relationship cannot be excluded. Thrombocytopenic purpura and aplastic anemia may occur. Confusional states, agitation, headache, blurred vision, optic neuritis and transient hearing loss have been reported, as have hyperglycemia, hepatitis, jaundice, hypersensitivity angiitis, pericarditis and several cases of anuria and hematuria. With long-term use, reversible thyroid hyperplasia may occur infrequently. Moderate lowering of the red cell count due to hemodilution may occur.

Dosage in Osteoarthritis: Initial: 3 to 6 tablets daily in divided doses. Usually unnecessary to exceed 4 tablets daily. A trial period of one week is considered adequate to determine the therapeutic effect of the drug. Maintenance: Effective level often achieved with 1 or 2 tablets daily, should not exceed 4 tablets daily.

In selecting appropriate dosage in any specific case, consideration should be given to the patient's weight, general health, age and any other factors influencing drug response.

Availability: Tan, round, sugar-coated tablets of 100 mg. in bottles of 100 and 1000.

Organ Transplants

THE IDEA OF joining the organs of one animal to another is an ancient dream of man. The powers to accomplish such a feat were once attributed to supernatural beings, and from mythology come tales of mermaids, minotaurs, harpies, chimeras and many other strange combinations of man and beast that were both worshipped and feared. In fact, we turn to mythology for some of the vocabulary of transplantation biology. The chimera of Greek mythology, a she-monster with a lion's head, a goat's body and a serpent's tail, is the biologic term for a mixture of tissues of different genetic constitution in an organism.

The first recorded scientific investigation of tissue transplantation from one animal to another was made in 1771 by the English surgeon, John Hunter.[1] He wrote that he "took a sound tooth from a person's head, then made a pretty deep wound with a lancet into the thick part of a cock's comb and pressed the fang of the tooth into this wound, fastening it with threads passed through other parts of the comb."

Basic Concepts

The "modern era" of the transplantation story begins in 1903 with the discovery by Danish biologist, C. O. Jensen, that tumors which arose spontaneously in mice could sometimes be propagated by grafting them from one mouse to another.[2] He recognized that mice of different "races" were not all equally susceptible to the growth of the tumors he was studying. At about the same time, Carrell was developing the techniques of vascular suture which made renal transplantation technically possible. The first successful long-term renal autotransplant was performed in a dog by Zaaijer in 1908.[3]

By 1914 Carrell had begun to realize that homografts behave differently from autografts, but it remained for Ingebrigsten and Little to show that the failure of homografts to survive was due to biologic differences between donor and recipient.[2,3] From 1923 to 1926 there was a flurry of renal homo- and hetero-transplantation studies in animals with no identification of the basic immunologic problems involved.

Medawar's Research

Finally, however, in 1944, in work which was to win him the Nobel prize, P. B. Medawar demonstrated the immunologic basis for the homograft rejection.[4] Working with skin homografts in rabbits, he outlined six general features which are characteristic of the homograft reaction[5].

Latent Period

Homotransplants of skin undergo normal primary healing and vascularization during a latent period following transplantation; during this time they provoke no specific reaction from their hosts.

Intensity of Reaction Inversely Related to Tissue Dose

Between the fourth and the eighth days an acute inflammatory reaction begins with vascular and lymphatic proliferation, followed by invasion of the graft by monocytes and lymphocytes. The graft and its bed show marked edema. The regional lymph nodes draining the site hypertrophy and show infiltration by similar cells. Inflammation reaches its peak and passes on to necrosis, with the stagnation and obliteration of the vascular system of the graft and the death of its cellular

*This is a medical student activity, wholly conducted by students and our student editor.

elements. The entire process of breakdown is complete within a span of four days. Medawar[4] reported the median total survival time to be 10.4 plus or minus 1.1 days, but this varied inversely with the tissue dosage.

Sensitized State

If a second graft from the same donor is applied following rejection of the first, it is rejected much more rapidly, with rejection nearly complete by the fourth day following transplantation. This accelerated rejection of a second graft from the same donor is referred to as the second-set phenomenon and is regarded as evidence of the existence of a sensitized state in the host.

Sensitivity Extends Through the Body

McKhann and Berrian[6] found that three to four days of contact was necessary to produce immunity in mice using skin grafts, and that it was not affected by repeatedly breaking the continuity of contact between graft and host by turning the graft in its bed or by moving the graft repeatedly to new sites on the host during the necessary three to four days of contact. Thus the development of immunity was not contingent on establishment of vascular continuity or the sensitization of a single set of regional lymph nodes, but the sensitivity extended with equal force throughout the vascular territory of the body.

Sensitivity Directed Against Donor

It was Medawar who established that the homograft reaction was an immunologic reaction, thereby disproving Ehrlich's hypothesis that inevitable differences in the chemical constituents between individuals accounted for the death of transplants on a purely nutritional basis. In support of his theory Medawar[7] cited the existence of a phenomenon superficially akin to the immunologist's secondary response.

Sensitivity Does not Distinguish Between Different Tissues from Donor

This second-set phenomenon shows exact specificity and may be induced either by a graft or by injecting living cells from the donor. Further, there exists a phenomenon analogous to passive transfer of immunity. Mitchison[8] showed that lymphoid cells from the regional lymph nodes of a mouse which has reacted against a local solid tumor homograft have the power to confer sensitivity upon a normal mouse. This second mouse will respond to a homograft of the same type of tumor with a second-set reaction. Finally, reactivity against homografts can be prevented by taking advantage of immunologic tolerance.

Humoral vs. Cellular

Although it is now generally accepted that the homograft reaction represents an antibody-antigen type reaction, it is not yet fully understood what role humoral antibodies play compared to cellular mechanisms, for sensitivity to grafts can routinely be passively transferred by cells, not by serum; but the passive transfer of immunity can occur to skin grafts in rabbits[9] and mice[10] by enclosing sensitized lymphoid cells within diffusion chambers which prevent escape of the cells. On the other hand, if a graft is enclosed within a similar Millipore chamber which prevents ingress of cells but supposedly lets in smaller particles, the graft survives much longer than would be expected.

These observations raise several questions: Are the cells which are observed infiltrating a rejecting graft drawn there by a specific antibody-antigen complex, or is this a non-specific response? Are the cells acting as manufacturing plants for antibodies? If so, why does hyperimmune serum not convey immunity to another member of the same species?

Specific or Non-Specific

Lymphoid cells labeled with tritiated thymidine and sensitized to the homologous skin donor were passively transferred to homografted isologous hosts. This led to an accelerated rejection in 39 of 46 cases.[10] However, though 33% of the cells in the suspension were labeled, only occasional labeled cells were found among the infiltrate at the site of rejection. Yet a similar accelerated rejection could not be brought about by simply transferring serum from sensitized hosts. Thus the cells were necessary for the reaction, but they did not actually have to be present at the site of rejection.

Manufacturing Plant for Antibodies

Another experiment took advantage of the fact that in sheep and goats, xenografts* produce a rejection pattern that is similar both temporally and histologically to that observed with allografts in these species. Hyperimmune plasma was obtained from sheep and goats 16 days after reciprocal skin grafts and six days after reciprocal kidney transplants.[11,12] Three hundred milliliters of this hyperimmune serum was then transferred to each of 10 sheep and 10 goats that had received reciprocal kidney transplants. The result was an accelerated rejection. Furthermore, I^{125}-labeled gamma globulin from the hyperimmune plasma showed a seven-fold increase in localization in the transplanted kidney when compared to the remaining host kidney. Passive transfer of serum from non-sensitized hosts did not accelerate the reaction, nor did the same protocol produce an accelerated rejection of renal allografts. Why should immunity to xenografts be transferred by serum while immunity to allografts is not? A possible explanation lies in the fact that the organs of an animal probably share a number of antigens which are common to the species, not just the individual. Hence when dog A produces antibodies against the kidney of dog B, he also produces antibodies against a number of antigens that are shared by all dogs. When hyperimmune serum is passively transferred to dog C, the common dog antigens contained in dog C immediately complex the available antibodies and no transfer of immunity occurs. Such a situation is not encountered in grafting between different species.

Antibodies Released into Serum

A recent experiment reported by D. S. Clark sheds further light on the relationship between humoral and cellular mechanisms.[13] A kidney was transplanted from dog A to dog B and allowed to remain for 72 hours. The grafted kidney was then removed and 600 r of total body irradiation was given. This is a lethal dose and prevents further leukocyte replication. When the white count had dropped to 0-500 cell mm^3, a second kidney from dog A was transplanted to dog B and allowed to remain for two to 12 hours. Recall that at this time dog B had whatever circulating serum antibodies might have been manufactured during the presence of the first transplant, but it no longer had any functioning, circulating lymphoid cells. This second kidney was observed to swell, become darker in color, and show a moderately reduced blood flow, but it continued to put out a concentrated urine of over 600 milliosmoles/kg, and there was no evidence of any leukocyte reaction within the kidney on biopsy.

After two to 12 hours, this second kidney was removed from dog B and transferred back either to its original host, dog A, or to an indifferent host, dog C. In either case, a rapid rejection with a florid, host-formed element response was observed; in effect, dog A ended up rejecting one of its own kidneys! As a control, dog B received a second kidney from dog D. This kidney was then transferred back to dog D or to dog E. No effect was observed. A further observation in this experiment was that complement consumption in the rejecting graft in dog A became measureable between the second and the twelfth hours. Apparently the second kidney from dog A underwent an antibody-antigen reaction while in dog B. Upon transfer back to dog A, the antigen-antibody complexes in the kidney caused the local infiltration of host lymphoid cells; the presence of these complexes is further evidenced by the drop in complement levels. The fact that cells are necessary for the production of these antibodies (i.e., they are not pre-formed like the blood group iso-antibodies) is shown by the lack of any effect on the kidney from dog D, to which dog B was not sensitized while cells were present.

This series of experiments seem to indicate that cells are necessary for the production of antibody, which is then released to the serum. The cellular infiltrate observed with rejection is a non-specific one; specifically sensitized cells do not have to appear at the graft site as a part of the rejection process.

Subcellular Factors

With the development of cell fractionation techniques, efforts have been made to identify

*See Test Your Word Score Page 1583.

the subcellular fractions involved in homograft sensitivity. Lawrence extracted a "transfer factor" from umanh leukocytes which allowed transfer of homograft sensitivity as well as delayed hypersensitivity.[14] This is another striking departure from the requirement in animals for intact cells to transfer homograft immunity. Lawrence found this transfer factor to be stable to storage in the frozen state, to repeated freezing and thawing, to deoxyribonuclease and ribonuclease and to lysis by distilled water. Mannick reported that ribonucleic acid extracted from sensitized lymph node cells led to accelerated rejection of donor-type skin homografts when given to normal recipients.[15]

Graft Antigen

The nature of the graft antigen which brings about the rejection process has received far less attention than transplantation antibodies. Dempster has suggested that natural tranplantation antigens do not exist.[16] He attributes responsibility for rejection to processes within the homograft itself as a reaction against unknown factors in the host. Other investigators have found, however, that the ability of various tissues to sensitize to a subsequent skin graft seems to correlate with their content of iso-antigens detectable serologically.[17] Hume further suggests that there is a definite chromosomal locus that controls transplantation antigenicity, and that there is a dominant and a recessive type.[18] The majority of experiments suggest that histocompatibility antigens are associated with both the external cell membrane and with internal membranous components of various cell organelles; but work in this field has been hampered by the lack of knowledge of the distribution of cell surface membrane material in the various fractions of subcellular studies.[17]

Tolerance

In 1945, Owen noted that most cattle twins at birth are erythrocyte chimeras, with each possessing some of the other's red blood cells.[19] Medawar and his co-workers showed that such cattle twins would accept skin grafts from each other, regardless of differences in sex, while grafts from third parties brought about a typical homograft rejection reaction.[20]

Burnett and Fenner proposed a general theory of immune response which accounted for the phenomenon of tolerance.[21] They suggested that body cells possess some type of "self-marker" and that during embryonic or early postnatal life (the exact time varying with the species) the capacity to recognize this marker is developed. Thus an antigen presented to the body before this capacity for self recognition had developed would cause that antigen to be interpreted as self in later life in that no immune response would be made to it.

Medawar and his colleagues originally defined tolerance as "the outcome of an induced central failure of the mechanism of immunological response brought about by the exposure of animals to antigenic stimuli before the maturation of the facility of immunological response."[22] They showed that dead cells elicit neither tolerance nor tissue transplantation immunity. Shortly thereafter it was demonstrated that tolerant mice were chimeras so far as their lymphoid cell populations were concerned.[23] The experiments of Smith and Bridges suggested that the duration of the tolerant state depended upon the persistence of the antigen.[24] This led Medawar to redefine tolerance as: "If an animal is exposed to antigen before it has developed the capacity to react against it, then the development of that capacity is delayed and, in the continued presence of that antigen, can be indefinitely postponed."[25] In his Nobel lecture, Medawar outlined the following three properties of the tolerant state:[26]

1. Tolerance is due to an alteration of the host, not to an antigenic adaptation of grafted cells.
2. The state of tolerance is systemic; a graft from a tolerated genotype will survive at any location on the body.
3. The state of tolerance is specific in distinguishing one individual from another, but not in telling one tissue from another; if skin is tolerated, so is any other tissue.

A tolerated graft retains its power to provoke immunity when transplanted to a normal environment, but tolerance may be abolished by inoculating a tolerant animal with immunologically active cells.

Graft Versus Host Reaction

In 1957 Billingham and Brent found that in certain strain combinations, attempts to produce tolerance in newborn mice produced a peculiar wasting disease and eventual death.[27,28] They concluded that this condition was the result of a reaction of the graft versus the host (GVH), and named the condition "runt disease." Graft vs. host reactions result when the recipient of a graft of immunologically competent cells is incapable of rejecting the graft. For example, in grafting from a homozygous donor (AA) to the F_1 hybrid between the donor and a dissimilar homozygote (BB), a situation results in which the host (AB) is incapable of rejecting the graft because the graft possesses no antigens foreign to the host. However, the host possesses antigens foreign to the graft, producing a graft vs. host reaction if the graft consists of immunologically competent cells. Such a reaction can be prevented by: (1) injecting isogenic adult splenic cells shortly before foreign cells are injected; (2) injecting adult cells preimmunized against the donor; or (3) passive transfer of serum-containing antibodies to the antigens present in donor cells.[29]

Graft Alterations

There is some evidence that extended survival of homografts may, at least in some cases, be due to an adaptive change in the graft rather than in the host. Woodruff and Simpson noted in rats that skin homografts on animals rendered highly but not completely tolerant could continue to survive with no change in the gross appearance, whereas a second graft from the same donor was completely destroyed.[30] If the long-tolerated skin graft is transferred to a normal recipient, it is regularly rejected. Billingham suggests that the mechanism for the decreased vulnerability of long-tolerated grafts may be due, at least in part, to complete replacement of the vascular endothelium of the graft by endothelium of host origin.[22] However, this does not adequately explain the rejection of the graft when it is transferred to another member of the same species.

Clinical Application and Problems

By far the greatest clinical experience and success in organ transplantation has been with kidneys, though recent advances have also been made in transplantation of the liver and the pancreas. Between 1936 and 1951 there were several unsuccessful attempts at renal homotransplantation in man, using cadaver kidneys. In 1953 the first transplant was done by Michon and Hamburger in France,[3] using a kidney from a living donor. By July 1967, at the latest report of the kidney transplant registry, there had been 1178 kidney transplants. Transplants have been attempted in newborn infants (two, both unsuccessful) and in individuals past 50.

Indications and Contraindications

Long-term transplants have been carried out in patients whose renal failure was secondary to pyelonephritis, glomerulonephritis, Goodpasture's syndrome, essential hypertension, malignant hypertension, polycystic renal disease, congenital hypoplasia, cortical necrosis, traumatic injury, bilateral benign renal tumors with massive hemorrhage, renal carcinoma, Kimmelstiel-Wilson's disease, Alport's syndrome, and horseshoe kidney.[3] Transplants in patients over 50 years of age have met with a high rate of mortality; therefore 50 is now regarded as an upper age limit for transplantation. Transplants are contraindicated in patients with uncontrollable generalized infections, irreversible brain damage, or a generalized nonrenal systemic disease likely to be fatal.[3]

Just as selection of recipients requires careful screening and selection, so donor selection must be done with great care. It is possible to transmit cancer, infectious hepatitis, histoplasmosis, thrombocytopenic purpura and delayed hypersensitivities through kidney transplants.[3] Evaluation of the potential living donor must be directed toward an assessment of general health, renal function and motivation to donate.

Histocompatibility

Obviously it is desirable to have the donor as compatible as possible antigenically with the recipient, and a number of different tests for

determining histocompatibility between donor and recipient are currently under investigation. It has been found that erythrocytes contain little if any transplant antigen. Failure of a transplanted kidney in the face of ABO incompatibility is probably due to the representation of ABO blood groups within the vasculature of the kidney, with subsequent thrombosis of the vessels due to attachment of blood group antibodies.[3,31] Hence proper matching of blood groups is important, but not directly because of the transplant reaction.

Skin Graft Test

Hume describes five general types of histocompatibility tests.[3] The simplest test is merely to transfer a skin graft from the intended donor to the recipient. This method suffers from several drawbacks, however. There is risk of immunizing the intended recipient against the intended donor. Furthermore, there is not an absolutely predictable relationship between the rejection of a skin graft and the rejection of a kidney.

The Third Man Test

A skin graft from the intended recipient is placed on a volunteer, who forms antibodies against the graft as it is rejected. Then skin grafts from several possible donors are placed on the volunteer and the donor is selected whose skin is rejected most rapidly, on the theory that he has shared antigens with the intended recipient, causing the accelerated rejection in the immunized volunteer. While the test demonstrates similarities between the intended recipient and donor, it does not indicate differences between them; furthermore, the test is subject to the reactions of the volunteer against each of the donors on the basis of his own incompatability with them.

Normal Lymphocyte Transfer Test

In this test blood lymphocytes from the intended recipient are transferred intradermally to the intended donor, and the size of the erythematous wheal is measured. The test is difficult to quantitate accurately and has not been shown conclusively to be related to ultimate graft survival.

Mixed Lymphocyte Reaction Test

When lymphocytes are incubated in tissue culture medium, some of the small lymphocytes become transformed into large immature cells which synthesize deoxyribonucleic acid, as demonstrated by the uptake of tritiated thymidine. If cells from a potential donor and recipient are placed together in a tissue culture medium there will be an increased transformation of small lymphocytes into large forms, and the degree of increase is related to the degree of antigenic dissimilarity between the donor and recipient. The difficulty with this test is that it is impossible to tell whether the donor is reacting against the host or vice versa.

Leucocyte and Platelet Typing

Leucocyte agglutination and cytotoxicity of various sera as end points can be used, but there are still deficiencies in the ability of these tests to separate donor-recipient pairs who appear to be compatible clinically from those who do not.

Requirements for a Useful Histocompatibility Test

The test should:[32]

(1) Be able to exclude any donor whose organs would elicit a particularly violent response in the recipient.
(2) Be able to pick out individuals from a group of possible donors whose tissue would be tolerated for the greatest possible time.
(3) Not lead to sensitization of a future recipient.
(4) Be quick to execute and have a high degree of discrimination.
(5) Be capable of use on debilitated or uremic patients.
(6) Be applicable to cadaver donors.

Currently only requirement number three can be met. Furthermore, the choice of living donors for any particular recipient is usually so limited that one does not have the luxury of choosing the most compatible donor.

Pathophysiology of Rejection

Clinically

The classic signs of threatened rejection

are fever, swelling and tenderness of the transplant and operative site, mild anorexia, and a fall in urinary output.[3,33] The laboratory provides further clues, including the appearance of lymphocytes in the urine, a change in serum lactic dehydrogenase, an increase in kidney size on X ray, a fall in the level of the second component of complement, a change in blood urea nitrogen and serum and urinary creatinine levels, and an increase in urinary alkaline phosphatase and lysozyme activity, as well as a fall in clearance for hippuran, Co^{57}, vitamin B_{12}, inulin, and creatinine.[33]

Microscopically

The tissues will show interstitial edema and infiltration with small lymphocytes, plasma cells, round cells, and pyroninophilic cells.[3,34,35,36,37] In the kidneys there is tubular damage with vascular necrosis and ischemia. Acute glomerular lesions, whether microscopic or ultrastructural, are rare.[3,34,35,38] The later rejection is seen in the course of the transplant, the more prominent the vascular lesions become. Beginning at 24 to 72 hours there is swelling of the endothelial cells of arterioles and the interlobular arteries, followed by general intimal thickening, medial atrophy and fragmentation of the internal elastic lamina of all vessels. Muscular hyperplasia of the small arteries and hyalinization of the arterioles become more prominent with time. Ultrastructurally, the glomeruli and distal tubules are normal.[37] There is an increase in the number of cytoplasmic vacuoles as well as cytoplasmic shedding in the proximal convoluted tubules in canine studies.[39] However, there is not generally a good correlation of changes in function with microscopic changes.[3]

Control of Rejection

It is imperative that these rejection episodes be controlled, and most of the clinical attempts at modifying the homograft response have centered about the use of irradiation and chemotherapeutics.

Radiation

Local radiation of the graft has proven particularly useful with transplants from unrelated donors as indicated by the one-year survival for kidney transplants from unrelated donors which showed 21% for those without local radiation versus 33% when radiation is used; the figures for two-year survival are 15% without radiation and 28% with radiation.[40] Radiation has not been shown to bring about a statistically significant improvement in survival where related donors were involved.

Chemotherapeutics

These may be divided into several classes: steroids, antimetabolites, alkylating agents, and antibiotics. Considerable species variation has been noted in the response to chemotherapeutic agents.[41] Steroids do little to modify homograft rejection in dogs, but in high doses they may abort the rejection of human renal homografts. Six-mercaptopurine (6-MP) was one of the earliest antimetabolites to show marked prolongation of skin and renal homografts; however, toxicity of the drug rendered management difficult. Azathioprine (Imuran) was found to cause less bone marrow depression while retaining the effectiveness of six-mercaptopurine. Imuran has been shown to significantly augment survival of human renal transplants and is now used almost universally in the management of transplant cases.[42] In general, the alkylating agents (mustards and ethylene amines) have been less effective than antimetabolites in direct suppression of the homograft response. The demonstration that certain antibiotics interfere with protein synthesis led to their trial in attempts to suppress the immune response. Most of the studies on suppression of the homograft reaction have utilized actinomycin C, which led to prolonged survival of renal transplants in dogs and man when used in conjunction with Imuran.

Complications of Drug Therapy

Physiologic

The use of chemotherapeutic drugs has led to a host of new problems. Gastrointestinal bleeding, secondary infections, diabetes, and cataracts have been not infrequent problems with steroid therapy. In studying 26 post-transplant patients ranging in age from 11 to 50 years, Hovland found that eight developed increased ocular pressures ranging

from 22 to 38 mm. Hg.[43] Twelve developed posterior subcapsular lens opacities. No significant correlation existed between the dose of prednisone and Imuran and the development of the lens opacities, however.

Infections

In a study of patients who died while receiving immunosuppressive therapy for organ transplantation, pulmonary infections were found to be present in 26 of 32.[44] Multiple infections were common, and the organisms found were not those usually responsible for clinical diseases; they included Candida, Aspergillus, Nocardia, Pneumocystis and Cytomegalovirus.

Imuran has been associated with pancreatitis, liver toxicity, and marrow hypoplasia. Thus in the case of liver transplants we have the unique situation of using a drug that is toxic to the liver to help promote liver function.

Transplant Lung[3]

This syndrome involves an alveolar-capillary block with low arterial pO_2 and O_2 saturation and normal arterial pCO_2. Physical findings in the lung are absent or minimal. The chest X ray may look like miliary tuberculosis, pneumonia or splotchy pneumonitis; or it may be normal. These changes are sometimes accompanied by threatened rejection of the kidney transplant. Histologically there is pulmonary capillary damage, edema, and round cell infiltration of the alveolar wall.

Present Morbidity

Despite the many problems which still exist, progress is being made in the field of organ transplantation. The latest data from the kidney transplant registry shows that where related, living donors were used there has been a one-year survival of 55% and a two-year survival of 48%.[40] The figures for unrelated donors were cited earlier. If one considers only the experience since January 1, 1965, the one-year survival rates for related donors is 65%, and that with cadaver donors 39%. Furthermore, many patients who had crippling neuropathy or nerve paralysis prior to transplantation have no significant difficulty with these problems just six months after transplantation.[46] Patients who have been nearly blind from hypertensive retinopathy have vision again. The anemia of renal failure disappears.

Conclusion

The transplantation of tissues and organs as a practical and safe method of dealing with disease still awaits further progress in many areas. Advances are being made in the storage and preservation of tissue. The identification of the major specific histocompatibility antigens of an organ remains an unsolved problem of profound importance. When this is solved, techniques of cross-matching will be required. Finally, the complex immunologic processes that are activated by the presence of foreign tissue within the body are not fully understood; when these processes are finally identified, there will be profound imp'ications not only for the area of transplantation, but for cancer research as well.

As the problems which currently complicate transplantation are solved, however, the ethical questions surrounding the transplantation of human tissue will loom ever greater. Nolan has pointed out that there are problems with regard to both the recipient and the donor.[47] For the present, one must realize that transplantation is a method of treatment which is still at the experimental stage and still of debatable value. One must further consider that in doing a transplant, one is submitting a patient to a treatment which includes the pain and inconvenience of major surgery and other unpleasant procedures, when the chances of restoring him to life may be relatively small. Finally there looms the question of who should be transplanted and who should be maintained on chronic dialysis.

With regard to the donor, one must ask when one is justified in subjecting a healthy person to the risks of surgery? When can one make the diagnosis of death and allow a cadaver kidney to be removed? In making such a decision one must be careful not to allow the need for the kidney to influence one's care of a potential donor. The answers to these questions extend far beyond the medical research laboratory.

A Program of Clinical Experience in Outpatient Education for Control of Diabetes Mellitus

The Diabetes Detection and Education Center, 916 East 15th Street, Minneapolis, Minnesota, has developed a program of medical and paramedical education for physicians, nurses, public health personnel, and dietitians. Classes are scheduled for the weeks of: November 4, November 18, December 2, December 16, and December 30. Rooms and meals are available at the Center at minimum cost.

For further information, contact D. D. Etzwiler, M.D., or C. B. Cohen, M.D., 916 East 15th Street, Minneapolis.

He isn't burdened by his hypertension or his therapy...

Butiserpazide® lowers blood pressure so smoothly that patients are often untroubled by either the disease...or treatment

BUTISERPAZIDE provides not only the classic thiazide/reserpine formula; it supplements it with the mildly sedative effect of BUTISOL (butabarbital).

Clinical comparisons have shown that many patients respond to this treatment with (1) smooth, uniform lowering of blood pressure[1]...at times *below* the levels attained with previous therapy[2]; (2) "striking" improvement in such symptoms as headache, nervousness, palpitation and dizziness[2]; plus (3) "...lowered incidence of drug side effects."[2]

And BUTISERPAZIDE offers an added advantage: the usual dosage is just 1 tablet once or twice daily. It is available in two strengths for dosage flexibility.

Are there any hypertensives in *your* practice who might find life a little pleasanter on BUTISERPAZIDE?

Contraindications: Sensitivity to any component, porphyria, peptic ulcer, ulcerative colitis, mental depression, renal impairment or shutdown. **Warnings:** Consider the possibility of sensitivity reactions in patients with history of allergy or bronchial asthma. Coated potassium tablets, sometimes administered in conjunction with antihypertensive therapy, may be associated with small bowel lesions, which have led to obstruction, hemorrhage and perforation. Surgery has frequently been required and deaths have occurred. Such tablets should be used only when indicated and when adequate dietary supplementation is not practical. They should be discontinued immediately if abdominal pain, distention, nausea, vomiting, or g.i. bleeding occur. *Use in Pregnancy:* Exercise caution, since thiazides cross the placental barrier and may cause fetal or neonatal hyperbilirubinemia, thrombocytopenia or altered carbohydrate metabolism; adverse reactions seen in the adult may occur in the newborn. Use reserpine in women of child-bearing age only when essential to patient welfare. Increased respiratory secretions, nasal congestion, cyanosis, and anorexia may occur in infants born to reserpine-treated mothers. **Precautions:** *Butisol* (butabarbital)—Exercise caution in moderate to severe hepatic disease. Elderly or debilitated patients may react with marked excitement or depression. *Hydrochlorothiazide*—May induce electrolyte imbalance; when used with digitalis or one of its glycosides and in patients with severe hepatic insufficiency, cardiac arrhythmias or symptoms of impending hepatic coma may occur. Discontinue and institute appropriate countermeasures if prolonged use produces hypokalemia or (likely with sodium restriction) hyponatremia and hypochloremic alkalosis. (Ammonium chloride, used to reverse hypochloremic alkalosis, is contraindicated in hepatic disease.) May produce elevated serum uric acid levels (and, infrequently, gout) or reduce glucose tolerance, altering insulin requirements in diabetics. *Reserpine*—Observe for signs or symptoms of peptic ulcer or ulcerative colitis. Discontinue at first sign of mental depression; keep in mind possibility of suicide. Exercise extreme caution in history of mental depression. May produce cardiac arrhythmias when used with digitalis and quinidine, or may precipitate biliary colic in patients with gallstones. Discontinue 1 to 2 weeks before surgery; inform the anesthetist in event of emergency surgery. Exercise caution in history of epilepsy. Discontinue 1 to 2 weeks before ECT. *General*—Exercise caution in coronary artery disease. **Adverse Reactions:** Dizziness, drowsiness, weakness, nasal congestion, leg cramps, nausea, palpitations, superficial skin bruises, palmar erythema, headache, dehydration, skin rash, "hangover," systemic disturbances, diarrhea, itching, vomiting, paresthesia, photosensitivity, pancreatitis, jaundice, xanthopsia, purpura, thrombocytopenia, leukopenia, agranulocytosis, aplastic anemia, anorexia, gastric irritation, abdominal cramping, constipation, glycosuria, vertigo, cutaneous vasculitis, orthostatic hypotension (potentiated by alcohol, barbiturates, or narcotics), increased salivation and gastric secretion, increased intestinal motility, loose stools, angina-like syndrome, arrhythmias, bradycardia, flushing, hypotension, nervousness, paradoxical anxiety, rarely atypical Parkinsonian syndrome, central nervous system sensitization (manifested by dull sensorium, deafness, glaucoma, uveitis, optic atrophy), dryness of mouth, syncope, epistaxis, weight gain, and impotence or decreased libido. **Usual Adult Dosage:** BUTISERPAZIDE®-25 or BUTISERPAZIDE®-50: 1 tablet daily or b.i.d. When used with other antihypertensive agents reduce dosage of both drugs about 50% and observe carefully for changes in blood pressure. ***Before prescribing or administering, see package insert.*** **References:** **1.** Johnson, H. J., Jr.: Penna. M. J. **67**:35, 1964. **2.** Coodley, E. L.: Curr. Ther. Res. **4**:460, 1962.

Butiserpazide®-25

PRESTABS®* Tablets

BUTISOL® (butabarbital) 30 mg.†; Hydrochlorothiazide 25 mg.; Reserpine 0.1 mg.

Butiserpazide®-50

PRESTABS®* Tablets

BUTISOL® (butabarbital) 30 mg.†; Hydrochlorothiazide 50 mg.; Reserpine 0.1 mg.

†**Warning:** May be habit forming.

*15 mg. of **Butisol** (butabarbital), plus the other ingredients, in outer layer; 15 mg. of **Butisol** (butabarbital) in a specially coated core for delayed release, to approximately equalize duration of action for all components.

FORT WASHINGTON, PA.

Save him from RHEUMATIC FEVER

Here are two ways:

1. If your child has a bad sore throat, don't wait – it might be "strep." Call your doctor. Treatment of "strep" infections usually can prevent rheumatic fever and the heart damage it sometimes causes.

2. Give to your Heart Fund. Your Heart Fund dollars support research and community service programs which can wipe out rheumatic fever and save thousands of young lives.

GIVE ...
so more will live
HEART FUND

ACHROMYCIN® V
TETRACYCLINE

Contraindications: Hypersensitivity to tetracycline.

Warning: In renal impairment, since liver toxicity is possible, lower doses are indicated; during prolonged therapy consider serum level determinations. Photodynamic reaction to sunlight may occur in hypersensitive persons. Photosensitive individuals should avoid exposure; discontinue treatment if skin discomfort occurs.

Precautions: Nonsusceptible organisms may overgrow; treat superinfection appropriately. Tetracycline may form a stable calcium complex in bone-forming tissue and may cause dental staining during tooth development (last half of pregnancy, neonatal period, infancy, early childhood).

Side Effects: *Gastrointestinal*—anorexia, nausea, vomiting, diarrhea, stomatitis, glossitis, enterocolitis, pruritus ani. *Skin*—maculopapular and erythematous rashes; exfoliative dermatitis; photosensitivity; onycholysis, nail discoloration. *Kidney*—dose-related rise in BUN. *Hypersensitivity reactions*—urticaria, angioneurotic edema, anaphylaxis. *Intracranial*—bulging fontanels in young infants. *Teeth*—yellow-brown staining; enamel hypoplasia. *Blood*—anemia, thrombocytopenic purpura, neutropenia, eosinophilia. *Liver*—cholestasis at high dosage.

Upon adverse reaction, stop medication and treat appropriately.

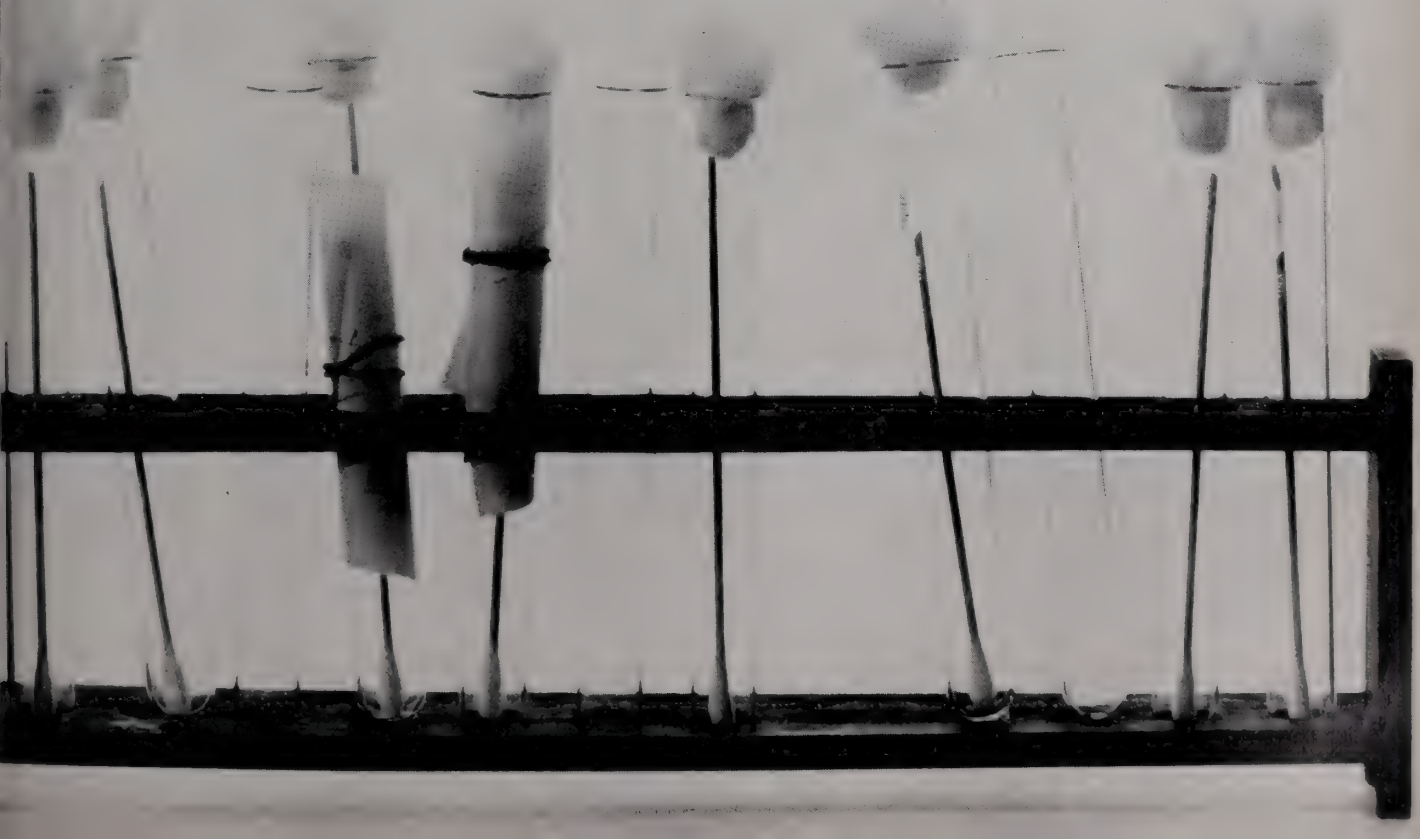
Suspected tetracycline-sensitive infection?

While waiting for the results of the sensitivity test, start the therapy likely to succeed...

Although of course it can't replace routine sensitivity testing, your prescription for ACHROMYCIN® V, in a way, provides the ultimate test of therapy under rigorous *in vivo* conditions.



Because ACHROMYCIN® V is effective in treating so many common infections—caused by strains of tetracycline-sensitive organisms—doesn't *stat* dosage of this time-tested antibiotic make good sense?

Serenity — *Joseph L. Teresi, M.D.*

DECEMBER, 1968

An antibiotic should work well in either acid or alkaline urine.

It isn't always necessary to adjust urinary pH in treating G.U. infections.

Not when the causative organism is a strain sensitive to DECLOMYCIN® Demethylchlortetracycline, as is often the case.

DECLOMYCIN remains stable and active in either acid or alkaline urine. So there's no need to acidify the urine to keep the antibiotic at work.

Why match the urine to the antibiotic...when you can match the antibiotic to the urine...by prescribing DECLOMYCIN. A b.i.d. dosage makes therapy convenient for your patient.

Effectiveness: DECLOMYCIN Demethylchlortetracycline should be equally or more effective therapeutically than other tetracyclines in infections caused by organisms sensitive to the tetracyclines.

Contraindication: History of hypersensitivity to demethylchlortetracycline.

Warning: In renal impairment, usual doses may lead to excessive accumulation and liver toxicity. Under such conditions, lower than usual doses are indicated, and, if therapy is prolonged, serum level determinations may be advisable. A photodynamic reaction to natural or artificial sunlight has been observed. Small amounts of drug and short exposure may produce an exaggerated sunburn reaction which may range from erythema to severe skin manifestations. In a smaller proportion, photoallergic reactions have been reported. Patients should avoid direct exposure to sunlight and discontinue drug at the first evidence of skin discomfort. Necessary subsequent courses of treatment with tetracyclines should be carefully observed.

Precautions: Overgrowth of nonsusceptible organisms may occur. Constant observation is essential. If new infections appear, appropriate measures should be taken. In infants, increased intracranial pressure with bulging fontanels has been observed. All signs and symptoms have disappeared rapidly upon cessation of treatment.

Side Effects: Gastrointestinal system – anorexia, nausea, vomiting, diarrhea, stomatitis, glossitis, enterocolitis, pruritus ani. Skin – maculopapular and erythematous rashes; a rare case of exfoliative dermatitis has been reported. Photosensitivity; onycholysis and discoloration of the nails (rare). Kidney – rise in BUN, apparently dose-related. Transient increase in urinary output, sometimes accompanied by thirst (rare). Hypersensitivity reactions–urticaria, angioneurotic edema, anaphylaxis. Teeth – dental staining (yellow-brown) in children of mothers given this drug during the latter half of pregnancy, and in children given the drug during the neonatal period, infancy and early childhood. Enamel hypoplasia has been seen in a few children. If adverse reaction or idiosyncrasy occurs, discontinue medication and institute appropriate therapy. Demethylchlortetracycline may form a stable calcium complex in any bone-forming tissue with no serious harmful effects reported thus far in humans.

Average Adult Daily Dosage: 150 mg q.i.d. or 300 mg b.i.d. Should be given 1 hour before or 2 hours after meals, since absorption is impaired by the concomitant administration of high calcium content drugs, foods and some dairy products. Treatment of streptococcal infections should continue for 10 days, even though symptoms have subsided.

Capsules: 150 mg; Tablets: film coated – 300 mg, 150 mg and 75 mg of demethylchlortetracycline HCl.

In the meantime...Ornade®

Prompt relief from nasal congestion and hypersecretion due to colds.

Before prescribing, see complete prescribing information in SK&F literature or *PDR*.
Contraindications: Glaucoma, prostatic hypertrophy, stenosing peptic ulcer, pyloroduodenal or bladder neck obstruction.
Precautions: Use cautiously in the presence of hypertension, hyperthyroidism, coronary artery disease; warn vehicle or machine operators of possible drowsiness.
Usage in Pregnancy: Use in pregnancy, nursing mothers and women who might bear children only when potential benefits have been weighed against possible hazards.
Note: The iodine in isopropamide iodide may alter PBI test results and will suppress I^{131} uptake; discontinue 'Ornade' one week before these tests.
Adverse Reactions: Drowsiness, excessive dryness of nose, throat or mouth; nervousness; insomnia. Other known possible adverse reactions of the individual ingredients: nausea, vomiting, diarrhea, rash, dizziness, fatigue, tightness of chest, abdominal pain, irritability, tachycardia, headache, incoordination, tremor, difficulty in urination. Thrombocytopenia, leukopenia and convulsions have been reported.
Supplied: Bottles of 50 capsules.

One capsule q12h for round-the-clock relief

Ornade® Trademark Each capsule contains 8 mg. of Teldrin® (brand of chlorpheniramine maleate); 50 mg. of phenylpropanolamine hydrochloride; 2.5 mg. of isopropamide, as the iodide.
Spansule® capsules brand of sustained release capsules

Today's physician sees more on NCME TV...

BETTMANN ARCHIVE

The first nationwide medical television service, NCME—The Network for Continuing Medical Education—brings you visually the important achievements of leading medical authorities. By means of closed-circuit television, this independent network provides your hospital or medical school with a complete videotape service that helps shorten the gap between new medical knowledge and its availability for clinical or teaching purposes.

NCME The Network for Continuing Medical Education

NCME TV Offers These Practical Benefits:

☐ Every two weeks a new 60-minute videotape dealing with three separate medical subjects is sent to participating institutions.

☐ Content and format of NCME telecasts fulfill criteria for postgraduate medical education, permitting American Academy of General Practice course credits under specified conditions.

☐ To help your institution make effective use of closed-circuit television, NCME offers a wide range of services and utilization aids, including: Technical consultation in setting up a closed-circuit system; advance program information on the contents of each telecast; display units to help publicize programs; expense-paid seminars to improve utilization of medical television.

☐ NCME programs are brief and may be shown as often as desired; you can view the telecasts at times that are most convenient, without disrupting your normal schedule.

☐ Frequently NCME makes available published papers related to subjects presented on closed-circuit television.

A recent NCME hospital telecast presented Philip N. Sawyer, M.D., Professor of Surgery and Head of the Vascular Surgical Service at Downstate Medical Center, Brooklyn, N.Y., in a demonstration and evaluation of "Gas Endarterectomy."

In this program, Dr. Sawyer performs the operation on a patient with gross occlusion of the right iliac, femoral and popliteal arteries.

In Dr. Sawyer's view, gas endarterectomy has several advantages over mechanical methods: the operation can be completed faster, causes less damage to the arteries and offers a more successful outcome.

NCME is an independent network supported by Roche Laboratories to increase the use of closed-circuit TV for medical education under direct hospital and school control.

If your hospital or school does not participate in the biweekly NCME program, information on the cost-free service may be obtained by writing to NCME, 342 Madison Avenue New York, N.Y. 10017

Presidents' Letter

George A. Sather, M.D.

O. L. Norman Nelson, M.D.

As the curtain is about to be lowered on a fast-expiring 1968, it is time to declare a brief moratorium on Medicine's problems and frustrations. The holiday fortnight affords an opportunity for recovery, or at least convalescence, from the wounds of Medicare, Medicaid, comprehensive health planning, utilization review, expansion of the medical school, a new medical school, et cetera; and a new legislative session lies just ahead.

On behalf of the Council and the officers of your Minnesota State Medical Association, we bring you greetings. May yours be a traditionally Merry Christmas and a Happy New Year.

George A. Sather, M.D.
Chairman of Council

O. L. Norman Nelson, M.D.

It's almost as if you were there to give an injection of penicillin

V-Cillin K®, Pediatric dependable oral penicillin therapy

Potassium Phenoxymethyl Penicillin

Description: V-Cillin K, the potassium salt of V-Cillin® (phenoxymethyl penicillin, Lilly), combines acid stability with immediate solubility and rapid absorption. Higher, more rapid serum levels are obtained than with equal oral doses of penicillin G.

Indications: Streptococcus, pneumococcus, and gonococcus infections; infections caused by sensitive strains of staphylococci; prophylaxis of streptococcus infections in patients with a history of rheumatic fever; and prevention of bacterial endocarditis after tonsillectomy and tooth extraction in patients with a history of rheumatic fever or congenital heart disease.

Contraindication: Penicillin hypersensitivity.

Warnings: In rare instances, penicillin may cause acute anaphylaxis which may prove fatal unless promptly controlled. This type of reaction appears more frequently in patients with a history of sensitivity reactions to penicillin or with bronchial asthma or other allergies. Resuscitative drugs should be readily available. These include epinephrine and pressor drugs (as well as oxygen for inhalation) for immediate allergic manifestations and antihistamines and corticosteroids for delayed effects.

Precautions: Use cautiously, if at all, in a patient with a strongly positive history of allergy.

In prolonged therapy with penicillin, and particularly with high parenteral dosage schedules, frequent evaluation of the renal and hematopoietic systems is recommended.

In suspected staphylococcus infections, proper laboratory studies (including sensitivity tests) should be performed.

The use of penicillin may be associated with the overgrowth of penicillin-insensitive organisms. In such cases, discontinue administration and take appropriate measures.

Adverse Reactions: Although serious allergic reactions are much less common with oral penicillin than with intramuscular forms, manifestations of penicillin allergy may occur.

Penicillin is a substance of low toxicity, but it possesses a significant index of sensitization. The following hypersensitivity reactions have been reported: skin rashes ranging from maculopapular eruptions to exfoliative dermatitis; urticaria; and reactions resembling serum sickness, including chills, fever, edema, arthralgia, and prostration. Severe and often fatal anaphylaxis has occurred (*see* Warnings). Hemolytic anemia, leukopenia, thrombocytopenia, and nephropathy are rarely observed side-effects and are usually associated with high parenteral dosage.

Administration and Dosage: Usual dosage range, 125 mg. (200,000 units) three times a day to 500 mg. (800,000 units) every four hours. For infants, 50 mg. per Kg. per day divided into three doses.

See package literature for detailed dosage instructions for prophylaxis of streptococcus infections, surgery, gonorrhea, and severe infections.

How Supplied: Tablets V-Cillin K® (Potassium Phenoxymethyl Penicillin Tablets, U.S.P.), 125 mg. (200,000 units), 250 mg. (400,000 units), and 500 mg. (800,000 units).

V-Cillin K® (potassium phenoxymethyl penicillin, Lilly), Pediatric, for Oral Solution, 125 mg. (200,000 units) and 250 mg. (400,000 units) per 5 cc. of solution (approximately one teaspoonful). [042567A] 800198

1700 Vaginal Hysterectomies

In A General Surgical Practice

LESLIE W. TASCHE, M.D.
Sheboygan, Wisconsin

MANY GYNECOLOGICAL procedures still seem to fall within the domain of the general surgeon in a community such as ours (45,000). One of the more difficult gynecological problems encountered is that of prolapse of the uterus. The Watkins interposition operation, the combined procedure of anterior and posterior colporrhaphy* and abdominal suspension of the uterus, and the Manchester-Fothergill were methods used to correct this condition, but were often failures.

Material

This report is based on 1700 consecutive vaginal hysterectomies performed between January 1943, and May 2, 1968. During this same period of time, 707 abdominal hysterectomies were done. All of these women were Caucasian and were private patients. The average age was 52.7 years. There were 16 women under 31 years of age and 16 over 80, the oldest being 91. The greatest number were between the ages of 40 and 60.

Indications

The three types of disability most commonly encountered, probably covering 90% of the cases, were varying degrees of prolapse, bleeding, and stress incontinence. Fibroids and cervical disease constituted most of the remaining 10%. Seldom was one of these conditions present alone. Gray[1] summarizes these multiple lesions to include benign cervicitis, stenosis of the cervical canal after cauterization or conization, enlargement of the uterus, retroversion, vaginal discharge, dysmenorrhea, dyspareunia, menorrhagia, metrorrhagia,* low backache, pressure pain and bearing-down sensations.

Classification of Prolapse

Prolapse was classified into three stages: the first degree was considered present when the cervix could be pulled down an appreciable

*See Test Your Word Score Page 1757.

distance from its normal position, the second degree when it could easily be pulled down to the outside, and the third degree when it protruded outside of the vulva or beyond without any pulling

Major Symptom Complexes

Prolapse and Bleeding

The two major symptom complexes, prolapse and abnormal bleeding, were divided into two age groups (Table 1).

It can be seen (Table 1) that abnormal bleeding brings more patients to their physicians in the early age group and prolapse in the older.

The cause of bleeding in the 555 cases could only be surmised by checking against the most prominent pathological findings (Table 2).

Urinary Symptoms

Stress incontinence, frequency and the inability to empty the bladder were present in 359 women. Those women with first and second degree prolapse had just as many troubles with their bladders as those with greater prolapse (Table 3). Why this should be is difficult to explain.

Carcinoma of the Cervix

If carcinoma of the cervix was strongly suspected by Pap test or previous biopsy and the lesion was thought to be in situ or early first stage, vaginal hysterectomy was done, removing a wide cuff of vagina.

Endometrial Carcinoma

If endometrial carcinoma was suspected from either the patient's history or a positive Pap test, and if the uterus was freely movable and not enlarged, with relaxation of the perineum, and if the patient was aged or obese or a poor risk, a vaginal hysterectomy was performed without curettement. Routine prehysterectomy curettage was not done; but if suspicion of carcinoma was entertained, curettage or biopsy was first performed. If cancer was found, the vaginal hysterectomy was postponed until a report on the tissue was obtained. Curettings and biopsies have been difficult to diagnose by our pathologists on frozen section. It was also felt that a so-called gentle curettement may well disseminate the cells of even a small malignancy.

Procedure

At first, a modification of the Mayo type of vaginal hysterectomy was performed but, because of the relative frequency of the development postoperatively of an enterocele or rectocele, or both, this was discontinued and the methods and principles established by Heaney[2] and Waters[3] were followed. Practically all of the 1700 operations were performed under intravenous induction of sodium pentothal followed by inhalation anesthesia.

Preoperative Preparation

There was no special vaginal preoperative preparation except for a thorough soap-and-water scrubbing followed by the application of tincture of merthiolate. The bladder was catheterized until empty and the labia were sutured to the adjacent skin. A second preparation of the vagina with tincture of merthiolate was then made. The cervix was pulled down with one or two Vulsellum forceps.

3rd degree prolapse	126	27	411	118

Entering the Posterior Cul-de-Sac

The bladder was freed from the cervix upwards and the peritoneal cavity was entered anteriorly. If this was at all difficult, this step was postponed until the peritoneal reflection could be visualized through the posterior peritoneal incision (Figure 1).

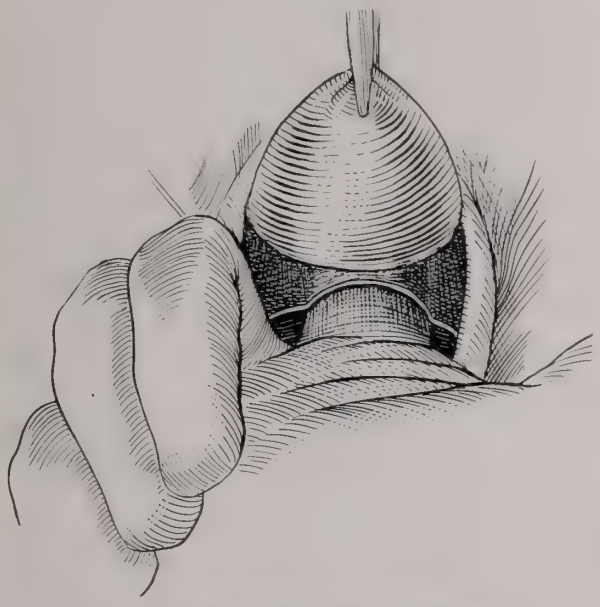

Fig. 1—Entering the posterior cul-de-sac.

Isolating the Ligaments

With the left index finger behind the lower cervical ligaments, a Heaney clamp was applied on the patient's left uterosacral and lower cardinal ligaments (Mackenrodt's) and the tissues divided (Figure 2).

Suturing and Dividing the Ligaments

A figure of eight double suture of chromic #2.0 was securely tied with the ends left long and clamped. The uterus on the patient's left side was then further freed by advancing the clamps upward and dividing and ligating each in turn, leaving the ends long and clamped (Figure 3). This was done until the tubes and the round and utero-ovarian ligaments were reached. It is very important that the bladder, ureter, and other tissues be pushed to one side with a retractor while this is being done. The procedure was then continued in the same manner on the other side (Figure 4).

Delivery of the Uterus

The ovarian ligaments and tubes were finally clamped on each side after bringing the uterus outside either anteriorly or posteriorly (Figure 5), whichever seemed the easiest. A weighted speculum was then placed in the vagina with the tagged ligatures lying on each side. The ovaries were examined; if any pathology existed it was removed.

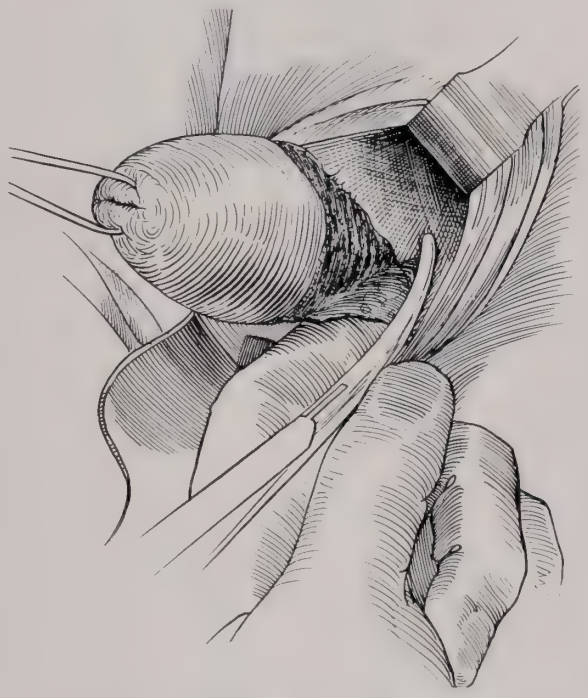

Fig. 2—Isolating and dividing the ligament.

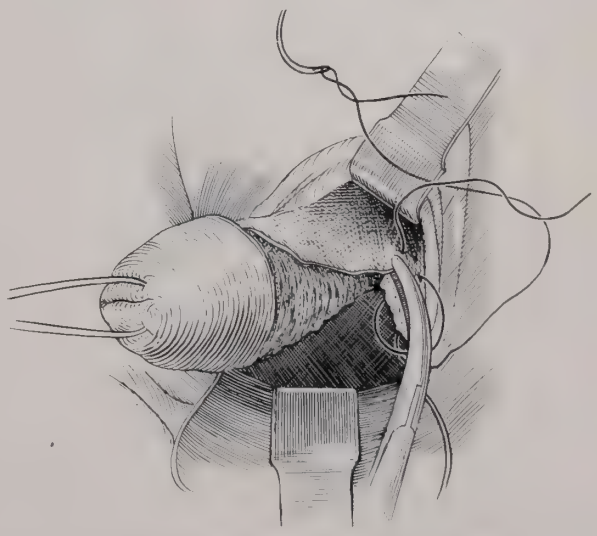

Fig. 3—Suturing of the ligament on left.

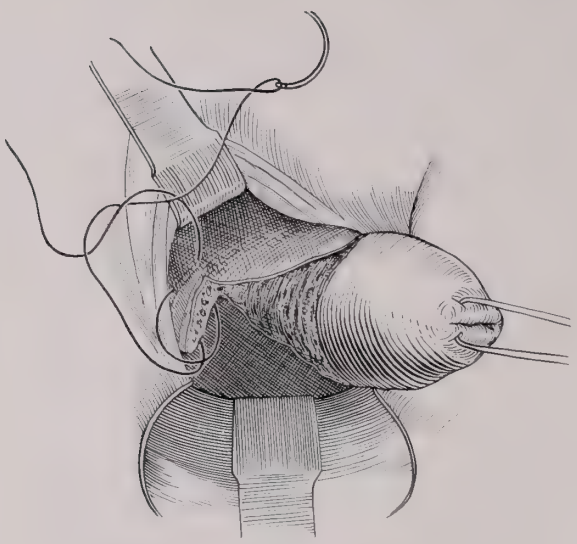

Fig. 4—Suturing of the ligament on right.

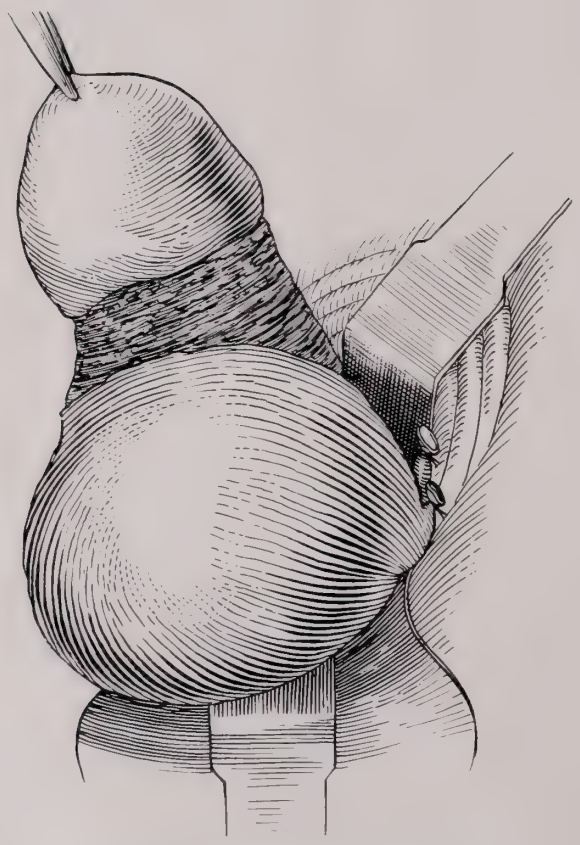

Fig. 5—Delivery of the uterus.

Closure of the Peritoneum

Excess posterior peritoneum was excised in order to eliminate the possibility of an enterocele developing. The peritoneum was closed with a purse-string suture, starting at the bladder peritoneum high up and going around, including the peritoneum of the left tube and accompanying ligaments, the broad ligaments, the uterosacral ligaments, and the peritoneum of the cul-de-sac (Figure 6). In the area of the cul-de-sac, the peritoneum was puckered with numerous small bites, continuing over to the patient's right side, including the uterosacrals and the peritoneum on up to the bladder, encircling the defect and ending at the beginning stitch. The purse-string suture was then pulled together, care being taken that the tubes and no other intraperitoneal organs were included (Figure 6). The purse-string suture was tightened with the stumps of ovarian ligaments and tubes, ready to be sutured together outside of peritoneal cavity.

Extraperitoneal Fixation of Ligaments

Next, one suture was used to bring the uterosacral ligaments together in the mid-line, incorporating the peritoneum of the cul-de-sac, and another suture to bring together the stumps of the round ligaments (Figure 6, inset). When this was done properly, all possible tied-off vessels were extraperitoneal, so that if an alarming drop in blood pressure occurred, it was almost impossible to have been due to intra-abdominal hemorrhage.

Closure of Vagina

The long sutures were cut short and any excess anterior vaginal wall was excised and then closed. If the bladder was found to be redundant and if stress incontinence had been a symptom, the bladder neck was plicated with a series of mattress sutures (Figure 7). In those cases of second and third degree prolapse where there was an excess of vaginal mucosa in the upper posterior part of the vagina, a wedge excision of this portion of vaginal wall was done. By doing this, combined with the purse-string closure of the peritoneum, the number of enteroceles and rectoceles developing postoperatively was markedly reduced. If there was generally relaxation of the entire

posterior wall, this wedge was continued down to the perineal repair, the latter being the final step.

Post-Surgical Precautions

Retention Catheter

At the completion of the operation, a Foley catheter #18 was inserted and left in place for about 60 hours. If, after its removal, the patient developed retention, the Foley was reinserted, kept in for 48 hours, and repeated several times if necessary. Also, an ordinary 4-by-4 sponge was inserted into the vagina to act as a pack to help control any oozing that might occur. This was removed in 24 hours.

Prophylactic Measures

The legs were wrapped with elastic bandages if varicosities existed. It has also been customary to follow this procedure with a daily intramuscular injection of 600,000 U of penicillin for four days.

After discharge from the hospital, all patients were instructed to douche at least once a day with a quart of warm water to which was added a tablespoonful of vinegar. They were allowed to walk stairs, bathe as they wished, but warned against straining at stool. They were examined vaginally at the office two weeks after leaving the hospital. Sloughs were removed and granulation tissue, if present, burned with the actual cautery. Office visits were repeated until the suture lines were completely healed and clean, which sometimes took up to eight weeks.

The average hospital stay was 8.2 days.

Combined Procedures

Because vaginal hysterectomy was done in a relatively short time, other procedures were occasionally combined with it, such as the following:

Inguinal hernia	7
Umbilical hernia	3
Femoral hernia	4
Hemorrhoidectomy	4
Breast biopsies	4
Thyroidectomy	1
Cholecystectomy	2

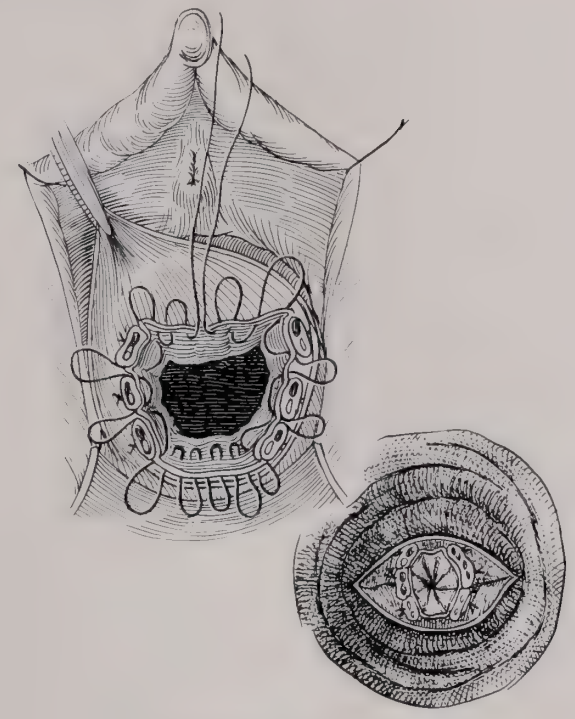

Fig. 6—Closure of the peritoneum

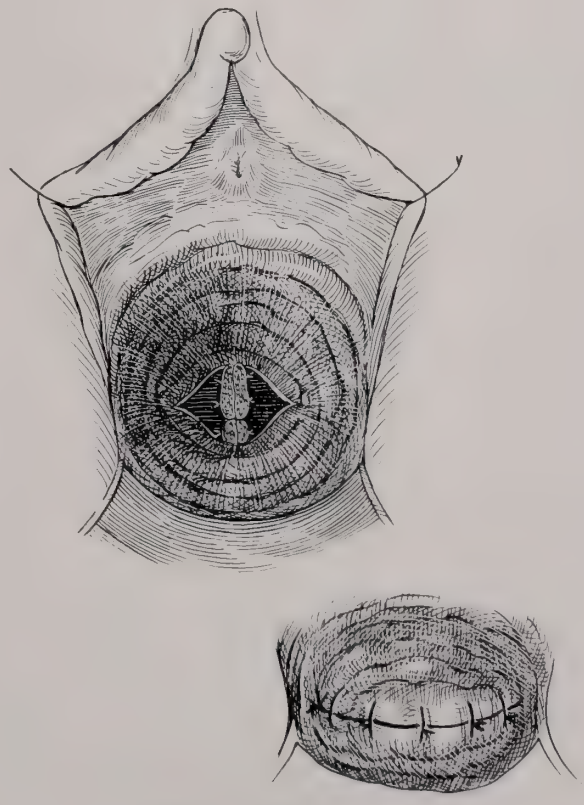

Fig. 7—Closure of the vagina

Complications Associated with Vaginal Hysterectomy

Inability to complete the operation occurred five times. The reason in two cases were large fibroids which were difficult to morcellate safely; morcellation was necessary in 33 cases. Twice the uterus was fixed to the anterior abdominal wall to such an extent that it could not be freed; and finally in one case there were so many dense adhesions from endometriosis that it seemed foolhardy to try to finish from below. In each case, repair of the perineum was completed, the abdomen entered and the uterus removed with relative ease, in no case with a prolongation of the patient's hospital stay.

In one case a sponge was lost; rather than traumatize the intestines looking for it from below, the abdomen was opened and the sponge removed. Other immediate complications were the accidental opening of the rectum in one case without any fistula formation; and the bladder was entered four times, once with a resulting vesicovaginal fistula which was successfully closed elsewhere.

Enlarged Ovaries

Oophorectomy was accomplished in 55 cases where the ovary was enlarged or diseased.

Transfusions

One hundred and fourteen (6.7%) patients required one or more transfusions. In many of these it was not because of immediate blood loss at surgery but because, prior to surgery, the patient's hemoglobin was deficient.

Postoperative Hemorrhage

Postoperative hemorrhage was a major problem and required packing or additional suture in forty-eight patients. Four times it was necessary to open the abdomen to control the hemorrhage. The high percentage of bleeding occurred in the patients under 45 years of age and seven days or more after surgery. This corresponds to the observations of Taylor and Hansen,[4] who believe that the number and severity of complications are almost directly proportionate to the youth of the patient.

Fever

One of the more numerous postoperative complications was fever. Ninety-two patients had a temperature of 102 degrees or more for two days or longer. In no case, however, was it necessary to incise or drain an abscess.

Urinary Retention

One hundred and nine patients had trouble with urinary retention, requiring further treatment with either recatheterization or re-insertion of the Foley catheter for a few days.

Miscellaneous Complications

There were three patients with non-fatal pulmonary infarcts, two with major thrombophlebitis, and one with a postoperative pneumonia. The 91-year-old patient, who had a complete procidentia and had surgery performed mainly because of her difficult custodial care, had a volvulus of the sigmoid a week after surgery and was operated upon by an associate. She survived and was discharged to live another year in comfort.

Early in this series, three gravid uteri were undetected and removed. Now all patients under 50 years of age have a pregnancy test.

There were no deaths in this series of 1700 cases. This fortunate outcome (and luck does play a role) corresponds with reports of other series of a thousand or more cases. Kempers, Hunter and Welch,[5] Andresen,[6] Hawksworth and Roux,[7] and Copenhaver[8] show a similar very low mortality rate, somewhere around 0.1%. In this series of cases, it is believed that at no time was a ureter injured.

During the same period of time, 707 abdominal hysterectomies were performed with five deaths, a mortality rate of 0.72%. Two of these deaths were due to massive pulmonary emboli, one from unknown cause or causes with a completely negative autopsy, and two from multiple complications. One of the latter patients had advanced bilateral ovarian cancer with peritoneal metastases.

Pathologic Findings

Malignancy was reported present by the pathologist forty-eight times. Of these malignancies, twenty-two were cervical carcinomas,

eight of which showed invasion; fourteen were considered in situ. Endometrial carcinoma occurred in twenty-three cases with penetration of the growth into the myometrium on fourteen occasions. One of these, a patient of 62, had had a curettage elsewhere and had been assured that no cancer existed. There were also two cases of leiomyosarcoma in fibroids, and one of sarcoma of the endometrium.

Results

Recurrence of Endometrial Carcinoma

The twenty-three cases of endometrial carcinoma have been checked within the past six months; in three there has been a recurrence. One was a frail 73-year-old woman who was operated on four years ago and died of a local vaginal recurrence one year ago. Another was a very obese patient who lived six years following the removal of her uterus for infiltrating adenocarcinoma of the endometrium and four years after a radical mastectomy for adenocarcinoma of the breast. Biopsy at laparotomy just prior to her death showed her pelvis to be filled with metastatic papillary cystadenomatous tumor tissue. The pathologist was unable to determine the primary source: uterus, breast, or ovary. The third was an obese woman of 69 who had an invasive adenocarcinoma Grade 3 and a marked prolapse. Tumor invasion of the blood vessels and lymphatics had been found at the time of surgery. She died within a year of extensive local recurrence.

These three cases of recurrence in twenty-three correspond with Pratt's[9] findings at the Mayo Clinic of 100 cases of carcinoma of the uterine fundus treated by vaginal hysterectomy with a five-year survival rate of 84%. Ingiulla and Cosmi[10] report a survival rate of 73.2% for more than five years in cases of simple vaginal hysterectomy for cancer of the corpus uteri among 112 patients so treated.

Recurrence of Carcinoma of the Cervix

Although in some of these twenty-two cases not enough time has elapsed to truly evaluate the end results, to date there has been only one recurrence, with death occurring five years after surgery. This happened early in this series, and this case was obviously poorly chosen for vaginal hysterectomy as it was a well-advanced lesion. A misinterpretation of the pathological report of the biopsy taken prior to surgery was responsible for this error.

Comments

A very careful history was always taken to be sure that the patient was not allergic to penicillin. For a while an attempt was made to do without penicillin; but, as morbidity seemed much greater without it, its use was resumed.

A late sequel, particularly in the early part of this series, was the development of an enterocele severe enough for the patient to seek surgical relief. Since the technique was changed and much more care was taken to excise the excess posterior peritoneum or enterocele sac and to close the peritoneal cavity with a purse-string suture incorporating all of the peritoneal surfaces plus the removal of a large wedge of the upper posterior vaginal wall, this complication has been markedly reduced. Stress incontinence has also been an occasional problem, and several patients have had to have a Marshall-Marchetti procedure performed upon them. Some of these women did not have this difficulty prior to surgery. Dyspareunia was an occasional complaint, but on questioning it was often found to have been present before surgery.

Conclusions

In conclusion, vaginal hysterectomy can be a procedure of very low mortality and low morbidity in the hands of a general surgeon. Sequelae such as enterocele and the development of stress incontinence have occurred; but with improved technique the number of these sequelae has been reduced. Routine pre-hysterectomy curettage is unnecessary and may at times be unwise and harmful by spreading an otherwise small and curable lesion. Finally, of all the operations a general surgeon performs, vaginal hysterectomy gives him the most satisfaction by offering the greatest relief to the largest number of patients.

Cervical Cancer Detection

OVER 167,000 WOMEN have been examined and have had cervical smears done by members of the Minnesota Academy of General Practice since this project began in Minnesota in September, 1965. From these examinations, 374 cases of carcinoma have been detected. Of the thirty-nine state Academies participating in this project, Minnesota ranks fourth, with 62.6% of its members participating, and first in number of patients screened, with 167,044 out of a total of 952,573.

The project was originated in February, 1965, to demonstrate the ability of general practitioners to practice effective preventive medicine among the middle income population. The objective of the project is to prevent death and disability from cervical cancer through increasing use of cervical cytology in the office of the family physician.

Prior to 1966, only 19% of Minnesota women had one or more Pap smears. As a result of this project, 47,044 women in Minnesota and 200,000 nationally have received their first Pap smear. Some of the 952,000 women who have been examined under this project are alive today because of it. Early evidence shows that the mortality rate of 14,000 per year from cervical cancer is also being reduced. Statistics to date show the highest incidence of carcinoma in this series in the 30-34 age group, followed by the 40-44 age group and the 34-39 age group in that order. In the 15-19 year age group, six carcinomas were discovered in 11,800 examined, or an incidence of .05%.

In both the Minnesota and the national studies the incidence of carcinoma in this project is 0.3% for those having the first smear, and 0.2% for those having repeat smears. The incidence ultimately will be somewhat higher because approximately two fifths of the suspicious smears have not had a final diagnosis reported. One half of these were lost to follow-up and the other half were recorded as diagnosis pending. Because the project has been in operation only three years nationally and two and one-half years in Minnesota, no data regarding the five-year follow-up are possible.

The Committee on Cervical Cancer Detection of the Minnesota Academy of General Practice believes that the project has been rewarding in many ways. It has demonstrated that general practitioners can practice office preventive medicine and that the majority of them are willing to submit to a moderate amount of extra paper work to contribute to the furtherance of medical knowledge.

East Indian Count

In ancient East Indian medicine the following classification of the human body was made. It consists "of six members (the four extremities, the trunk, and the head), and has 7 membranes, 7 segments, 70 vessels, 500 muscles, 900 sinews, 300 bones, 212 joints, but only 24 nerves, and 9 organs of sense, etc. The vessels contain not only blood, but they carry also bile, mucus, and air about through the body. Of the nerves, which take their origin from the navel, 10 ascend, 10 descend, and 4 run transversely; as soon as the ascending nerves reach the heart, however, they divide into 30."*

Ascariasis

DAVID CARLSON, M.D.*
HORACE H. ZINNEMAN, M.D.*
Minneapolis, Minnesota

VARIOUS PARASITIC DISEASES have been and are now being imported into the United States through military and civilian personnel upon their return from Southeast Asia. The most common of these diseases is malaria, followed by ancylostomiasis,† giardiasis,† and amebiasis. Our recent experience with the less common ascariasis appears to merit the attention of the physicians of this area and also to indicate a review of other complications of the disease which may confront the physician.

Case Report

A 20-year-old Marine corporal was admitted to the hospital with a twelve-hour history of crampy mid-abdominal and right upper quadrant pain, watery diarrhea and vomiting. The symptoms had followed a heavy meal. Prior to their onset the patient had experienced no gastrointestinal disturbances. He had returned from Vietnam ten months before and to his knowledge had not contacted any parasitic disease while there. He admitted, however, to having sampled native food quite frequently.

Physical examination was not remarkable. No abdominal tenderness, distention or pain was present.

Laboratory data included a hemoglobin of 15.2 gm%; the WBC was 8,300 with a normal differential count and 1% eosinophils. BUN, creatinine, 2-hr p.c. glucose and liver function tests were within normal limits. The stool examination was negative for occult blood.

Hospital course: on the second hospital day the patient passed a large number of worms in his stool. To his knowledge this had never occurred before. The worms were identified as Ascaris lumbricoides; ascaris ova were also recovered from the stools. Special stool examinations for E. histolytica and a cholecystogram were negative; the upper gastrointestinal and small bowel x-ray series revealed a heavy infestation of the jejunum with round worms (Figure). The patient was treated with Piperazine 3.5 gm by mouth on two successive days, and large numbers of adult ascarides were passed in the stool. Subsequent stool specimens were negative for ascaris ova but were positive for Giardia lamblia. Following treatment with Atabrine 100 mgm b.i.d. for five days, the *Giardia lamblia* disappeared also.

The patient was returned to duty with our recommendation that he be followed at his duty station for possible recurrence.

*From the Department of Medicine, Minneapolis Veteran's Hospital, and University of Minnesota School of Medicine, Minneapolis, Minnesota.

†See Test Your Word Score Page 1757.

Incidence

Ascariasis is estimated to parasitize 664 million people over the world[1], and together with hookworm represents more than half of all human-worm infestation[2]. Three fourths of all cases of ascariasis exist in Asia, and incidence rates for Oriental countries, Ceylon and the Philippines are reported as ranging from 15 to 79 percent of the population[3]. In rural southwest Korea there is a 90% incidence[4]; and in Cape Town, South Africa, 70% of negro children are infected with *A. lumbricoides* after the first year of life[5]. Ascariasis is commonly seen in Vietnam[6]. An estimated three million cases exist[1] in North America; highly endemic areas are the Appalachian mountains and adjacent regions, southwestern North Carolina, and south central Louisiana[3]. Under conditions of very poor sanitation virtually an entire population can be infected[6].

The Parasitic Nematodes

The largest of the parasitic nematodes, Ascaris lumbricoides is creamy-white in color with fine, circular striations on its cuticle[2]. The female is 20 to 35 cm long and about as thick as a lead pencil; the male is more slender, up to 30 cm in length, and can be distinguished by an incurved tail[7].

The Eggs

The majority of eggs require three weeks

Fig. 1. Roentgenologic examination of the gastrointestinal tract with barium contrast medium shows outlines of multiple roundworms throughout the small bowel.

for maturation. In a moist, shady habitat and moderately warm temperatures, first-stage larvae may develop in nine to thirteen days[8], while under unfavorable conditions (i.e., direct heat and excessive dryness) the eggs may remain dormant but viable for two to four years. Infection occurs by mouth, cutaneously[8].

The Larvae

After ingestion of embryonated eggs, digestive juices act on the shell, and larvae are hatched in the duodenum[7,8]. They then penetrate the duodenal wall, enter blood or lymphatic vessels, and are carried into the systemic circulation and to the lungs, where they break through pulmonary capillaries and into the alveolar spaces. There they grow, undergo two successive molts, and after ten days migrate through the respiratory passages to reach the esophagus and small intestine[3]. The worms are mature and begin laying eggs 60 to 75 days after initial ingestion of the ova[7,8]. The mature female has been estimated to produce 200,000 eggs daily[9]. Nutrients are obtained from sucking intestinal fluids. The jejunum and upper ileum are the favorite habitation sites[7].

The Invasion of the Larvae

Invasion of the larvae into the portal circulation results in mild hepatic hemorrhages; petechial hemorrhages and inflammatory changes in alveolar walls follow migration of the larvae into the alveolar spaces[3]. Simultaneous invasion of the lungs by a large number of larvae may cause a severe pneumonitis which is a form of Loeffler's syndrome[9,10].

The Clinical Symptoms

Symptoms include fever, substernal chest pain, nonproductive cough in severe cases, even hemoptysis and dyspnea[8,10]. Wheezing and musical rales are heard on examination of the lungs, and urticaria or papular skin eruptions may occur. An eosinophilic leukocytosis of 30 to 70 percent is seen in the acute phase[10]. Patchy areas of consolidation may appear on a chest roentgenogram[8]. Ascaris antigens are extremely potent sensitizing agents and will cause urticarial reactions and asthmatic symptoms in nonatopic workers employed in laboratories where ascaris worms are dissected and processed[10]. It is estimated that one sixth of ascaris-infected persons have clinical symptoms.

Organ Involvement

Another pulmonary manifestation reported is that of a solitary pulmonary nodule consisting of a granulomatous reaction surrounding ascaris eggs which were thought to have been inhaled.

Occasionally larvae reach the *general circulation* and provoke symptoms of varying severity. Lodgement of larvae in the *eye* has been associated with retinitis and palpebral edema. Penetration of larvae to the *brain* may cause convulsions, meningitis and encephalitis. Involvement of the *spinal cord* and *kidneys* may occur; and aberrant larvae may occasionally produce the visceral larvae migrans syndrome, particularly in children[8,9].

Chronic Involvement

Chronic ascariasis may be manifested by seemingly nonspecific *gastrointestinal complaints,* such as epigastric discomfort or colic, diarrhea, nausea, vomiting, low-grade fever, anorexia, and palpable abdominal mass. Weight loss and nervous symptoms such as irritability may also be present[3]. It has been reported that ascaris-infected children are physically less developed and *mentally less alert* than uninfected ones, and that nutrition and scholastic ability improve following treatment[8].

Acute Involvement

A relatively small proportion of patients develop acute ascariasis, often a complication of migration of the worms from the jejunum and ileum. Migrating worms may enter the stomach and be vomited, or they *may enter the nasopharynx and eustachian tube* or the trachea, causing suffocation. Large infestations may induce severe toxic symptoms, such as convulsions in children[8]. The most common complication of ascariasis is obstruction of the small intestine[5,12].

Medical treatment can usually prevent serious complications, but surgical intervention is necessary if medical treatment is not effective[12].

Intestinal Tract

Obstruction is usually caused by an entangled mass of worms completely blocking the

lumen. Our patient's acute episode appears to have been a partial *intestinal obstruction.* Worm secretions can provoke an inflammatory reaction in the bowel wall, and toxic decomposition products may cause *bowel wall necrosis*[5]. *Volvulus and intussusception* of the small intestine may occur [4,13] and appendicitis may develop following migration of an ascaris into the appendix[4,5].

Biliary System

Biliary obstruction has occurred, particularly in China[5] and Korea.[14] In the majority of cases, a single worm has been found in the *common duct,* but from two to 10 parasites are not unusual and from 30 to 45 ascarides have been reported.[14] Even *biliary calculi* formed from dead worms or ascaris eggs have been encountered[4,15] and may produce a clinical picture of acute cholecystitis or cholelithiasis.[3] *Hepatic abscesses* due to migration of ascarides to the liver may occur; these require surgical treatment.[16]

Pancreas

Acute *pancreatitis* may follow obstruction of the ampulla of Vater or the pancreatic duct by an ascaris. Complete, unrelenting obstruction may cause fatal *hemorrhagic pancreatitis;* but more often obstruction is temporary and the worm retreats.[3,5,8] Deep penetration of a worm into the pancreatic duct may result in formation of a *pseudocyst.*[5]

Unusual Manifestations

Other more rare complications include perforation of the intestine, bile or hepatic duct with peritonitis, diverticulitis, pleural empyema, genitourinary tract involvement and the crawling of worms out of tuberculous sinuses from psoas abscesses and from the spine.[4,8] Mesenteric infarction due to venous obstruction with mature ascarides which were thought to have developed aberrantly in the mesentery has recently been documented.[17]

Significant malabsorption from the small intestine does not occur unless tremendously large numbers of parasites are present.[18] Of 731 consecutive acute abdominal emergencies in children aged one to 12 in Cape Town, ascariasis accounted for 12.8% of the cases, ranking second only to appendicitis.[5] In that study, 37.5% of the deaths from acute abdominal emergencies were due to ascariasis. Prior to the use of Piperazine, as many as 66% of patients with intestinal obstruction due to Ascaris died, including some adults.[12]

Diagnosis

Diagnosis in routine cases depends on identification of ascaris ova in stool preparations. When pulmonary ascariasis is suspected as a cause of Loeffler's syndrome, diagnosis can be made by recovering larvae in early morning gastric aspirates,[19] or from sputum samples.[10] Hypereosinophilia is thought to appear during and shortly after the larval stages in the lung, often subsiding to near normal levels after the worms reach maturity[20] and to completely normal levels after eighteen months. Eosinophilia has been reported more prominent in children up to age 10 than in older individuals.[20] Eosinophilia occurs in up to 10% of chronic ascariasis cases; but its incidence is less than 3% in three fifths of all patients.[3] Intradermal skin tests and precipitin reactions have been employed.[21] The radiologic sign of Aiken and Dickman, "wisp-like radiolucent lines in a somewhat parallel manner with a shadow representing a mass of ascaris" seen on plain films of the abdomen, is of value in determining the etiology of acute intestinal obstruction.[12,13] Following a barium meal the worms displace the barium or barium is retained in the worms' intestinal tract after the host has evacuated the barium; this phenomenon is sometimes responsible for the incidental discovery of ascariasis.[9]

Treatment

Piperazine is the most effective drug for eradication of ascariasis.[3,8] In recommended doses it is nontoxic. When given to adults in two 3.5-gram doses 24 hours apart, cure rates approximating 95% can be achieved.[22] Ascarides are usually excreted from the first through the third day after treatment. Piperazine produces narcosis and relaxation of the worms, and they are presumably passed because of inability to maintain their position in the small intestine by pressure against the intestinal wall and resistance to intestinal peristalsis.[23] Other effective drugs are Bi-

phenium hydroxynaphthoate, Thiabenzadole[24] and Hexylresorcinol.[3]

Efforts in the control and prevention of ascariasis appear to be herculean, considering the extent of the problem. Improvement of living conditions with use of clean, sanitary toilets is essential. Where night soil is used as fertilizer, raw vegetables and fruits should not be eaten without processing. In some parts of Asia, air-borne ascaris infection is suspected.[8]

Summary

A heavy infestation with Ascaris lumbricoides was the cause of a partial intestinal obstruction in a serviceman who had returned from Vietnam 10 months prior to the onset of symptoms. The intestinal obstruction relented spontaneously and medical treatment with Piperazine succeeded in the elimination of the helminthic infestation.

Why Does the Patient Complain

The big mistake that doctors make is in jumping from complaint to symptom; by translating in this way one makes an impersonal case out of a human being. Thus we miss several links in complaint formation. It has already been emphasized that both the patient and the doctor contribute to the manner in which the complaint is presented, and on both sides there are preconceived subconscious notions that are not clearly understood. If we wish to analyze this complicated situation, we must retrace our steps. We must realize that the question to be decided is not what sort of disease is behind the symptom the patient complains of; the real medical question is: why does the patient complain? (i.e., what is really bothering the patient?)*

Nobel Prize Winners In Medicine and Physiology 1956

Andre Cournand, Werner Forssmann, Dickinson Richards

"For their discoveries concerning heart catheterization and pathological changes in the circulatory system."

"In emergency conditions which menace patients by interruption of cardiac activity, such as acute collapse in cardiac patients or in anesthetic episodes and poisoning, one is forced to undertake a rapid local drug treatment. In such cases, the sole remedy is often an attempt at intracardiac injection which then occasionally can be life-saving. . . . These considerations have led me to seek a new way whereby one can penetrate into the heart without danger, and so I have investigated the probing of the right heart, approaching it from the venous system.

"After the success of experiments on cadavers, I undertook the first investigation in living humans through self-experimentation. First of all, in a preliminary experiment I allowed myself to be punctured in the right elbow vein using a large-bore needle. One of my colleagues kindly placed himself at my disposal for this purpose. I then introduced a well-oiled ureteral catheter through the cannula into the vein. The catheter was then easily introduced for a distance of 35 cm. of height. Because further catheterization appeared to my colleague to be risky, we interrupted the experiment, although I felt completely well. After one week I undertook alone a further experiment. Because venipuncture with a thick needle in oneself appeared technically too difficult, I made a venesection after local anesthesia in my left elbow and introduced the catheter without resistance for its whole length, 65 cm. This distance appeared to correspond to the path from the left elbow as far as the heart. During the introduction of the catheter, I had the feeling of gentle warmth only during the sliding along the wall of the vein, similar to the feeling during an intravenous injection of calcium chloride. By intermittent movement the catheter beat against the upper and rear wall of the clavicular vein, and I noticed an especially intense heat behind the collarbone under the insertion of the muscles of rotation of the head; at the same time, probably through irritation of vagal branches, there was a gentle cough.

"The position of the catheter was proven by x-ray and indeed I observed the tip of the catheter itself in a mirror held in front of the illuminated screen by a nurse.

"The trip from operating room to x-ray department, which is an unusually long distance in our establishment and during which I had to ascend stairs, covering the distance on foot with the probe lying in the heart, was not associated with unpleasantness. The introduction and removal of the catheter was completely painless, only being associated with the above described sensations."

Forssmann's paper describing his "probing of the heart" was published in 1929.*

A decade after Forssmann, Cournand and Richards introduced his technique into their research on the physiology of the heart and lungs, and from then on they and their colleagues demonstrated its usefulness in one brilliant study after another.†

Cutaneous Clues to Visceral Cancer*

HAROLD O. PERRY, M.D.†
JOSEPH M. KIELY, M.D.‡
CHARLES G. MOERTEL, M.D.‡
Rochester, Minnesota

IN THESE DAYS of more refined laboratory techniques for diagnosis of disease, a careful examination of the skin is often overlooked as a means of determining the presence of an underlying malignant neoplasm. A possible relationship exists between certain cutaneous changes and underlying visceral cancer, lymphoma, or leukemia. In the future, more detailed information about these skin diseases may establish with greater assurance their specificity as clues to visceral neoplasms.

Arsenism

The ingestion of medicinal arsenic preparations may result in palmar and plantar hyperkeratosis, hyperpigmentation of the skin, cutaneous cancers, and sometimes even visceral carcinoma. Incidental exposure to arsenic in drinking water and in some occupations is recognized and may produce similar changes. Trivalent inorganic arsenic is usually responsible for these changes, although organic forms of the element are sometimes implicated.

A latent period, usually of several years, follows the ingestion of the arsenic before cutaneous evidence of arsenism, namely, the keratosis and pigmentation evolve. Additional time usually elapses before the accompanying visceral cancer develops. The quantity of arsenic required for these changes varies greatly from patient to patient, as does the latent period before the development of arsenical cancer.

Dermatological Findings

Keratoses developing subsequent to arsenical ingestion occur predominantly on the palms and soles although they may be found elsewhere on the body (Figure 1). Initially these are barely visible but readily palpable hyperkeratotic papules; later they become larger and verrucous,§ with surrounding callus formation. Exfoliation and fissuring of the palms and soles may also be present.

*Read at the Mid-Winter Clinical Sessions of the American Medical Association, Houston, Texas, November 28, 1967.
†Mayo Clinic and Mayo Foundation: Section of Dermatology.
‡Mayo Clinic and Mayo Foundation: Section of Medicine.
§See Test Your Word Score Page 1757.

Hyperpigmentation of the skin may accompany the hyperkeratoses as an additional sign of systemic arsenism (Figure 2). All the skin and mucous membranes may be involved, but the hyperpigmentation is more severe in areas that are usually more pigmented, namely the nipples, axillae, groin, and perineum. The pigmentation is generalized in distribution and mottled in appearance.

Dyskeratotic changes in some of these lesions may occur, resulting in ulcerating squamous-cell epitheliomas. In addition, both squamous-cell epitheliomas and superficial basal-cell epitheliomas may arise anywhere on the skin, independent of the hyperkeratoses.

Development of Neoplasia

At the same time or later, arsenical cancers involving the urogenital, oral, esophageal, and respiratory epithelia may develop.

Sommers and McManus[1] reviewed the development of cancers of the skin and internal organs in 27 patients who received injections of arsenic and found multiple skin cancers in all. In the six cases in which autopsy was done, separate additional internal cancers were found in four, three at multiple sites. In five other patients, death was ascribed to cancer; but in the absence of autopsies none were proved pathologically.

Dobson and Pinto,[2] in their study of arsenical carcinogenesis, emphasized that patients who ingest arsenic have a higher incidence of plantar and palmar keratoses. Their retrospective study considered the incidence of palmar keratosis in a group of 671 patients with cancer. They compared this incidence to the occurrence of palmar and plantar hyperkeratoses in a noncancer-bearing population matched by age and sex. In the group with cancer, 46% of the men and 26% of the women had keratosis, compared to 11% of the men and 5% of the women in the control group. A study of the histories of arsenical

Fig. 1—Arsenical keratoses on palms seen as punctate hyperkeratoses or larger hyperkeratoses that sometimes may be translucent. This patient, in addition to palmar and plantar keratoses, had a papillary, transitional cell epithelioma (grade 1) of the bladder.

ingestion of these cancer patients revealed that 13% had been exposed to arsenic as compared to 10% of the control group. This difference seemed insignificant.

These authors concluded that if arsenic is responsible for the production of palmar and plantar keratoses and if patients with internal cancer have a higher than normal incidence of palmar and plantar keratoses, then the possibility exists that arsenic is an important carcinogen for internal cancers.

Generalized Plane Xanthoma

Lynch and Winkelmann[3] have pointed out that generalized plane xanthoma, a less frequently recognized form of xanthomatous disease, is associated with other diseases of the reticuloendothelial system.

Dermatological Findings

Generalized plane xanthoma consists morphologically of yellow to yellow-brown macular areas or slightly elevated plaques that occur predominantly on the eyelids, lateral aspects of the neck, and the upper part of the trunk. The lesions may be distinct or visible only with tangential lighting. This type of xanthoma readily contrasts with papular and nodular xanthomas as seen in xanthoma disseminatum, xanthoma tuberosum, eruptive xanthoma, xanthelasma,* and xanthomas of the tendon sheaths. Some patients with generalized plane xanthoma have associated xanthelasma palpebrarum.

Plane xanthomas may be associated with other xanthomas in patients with increased blood lipid levels related to a familial pattern or with biliary cirrhosis. Generalized plane xanthoma, however, may also occur with normal lipemic serum and without the associated features previously noted.

The histologic features in plane xanthomas are distinctive but not diagnostic. Histiocytic foam cells in aggregates of only a dozen can be seen throughout the upper dermis, predominantly in a perivascular location. Giant-cell formations, atypical for Touton giant cells, may at times be striking.

Development of Neoplasia

Altman and Winkelmann[4] initially studied a group of these patients, but the relationship with systemic disease was not then apparent. Subsequently, Lynch with Winkelmann[3] documented an association between generalized plane xanthoma and diseases of the reticuloendothelial system. They reported on two patients with generalized plane xanthoma, one in whom granulocytic leukemia developed and the second in whom leukemic lymphocytic reticuloendotheliosis developed. On reviewing the literature, these authors noted that 20 patients, including their own, had generalized plane xanthoma. From the historic data, onset of the lesions occurred during childhood in four patients and during the adult years in 16. Multiple myeloma developed in six men and two women. Information was not available in all cases, but the xanthoma was recognized as being present for as long as 18 years before the myeloma was discovered. Two adult patients also had xanthomas, apparently

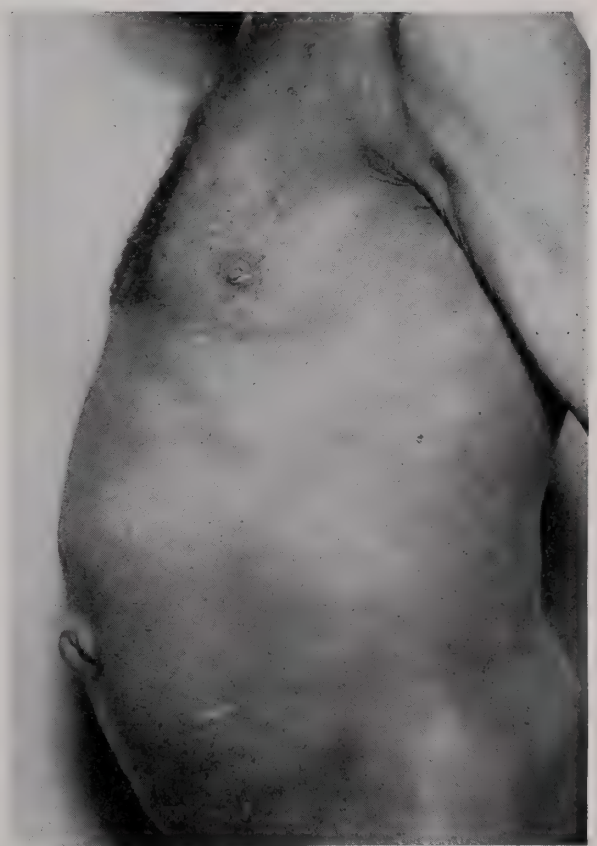

Fig. 2—Generalized hyperpigmentation, with mottled pattern and white depigmented areas, the so-called raindrop pattern that is characteristic of chronic arsenism. This patient also had cirrhosis of the liver, proved histologically, which was considered a complication of his chronic arsenic ingestion.

*See Test Your Word Score Page 1757.

present some years before discovery of their reticuloendothelial disease.

In addition to the 20 patients with typical generalized plane xanthoma, three were found with atypical, but suggestive, features of plane xanthoma. The two children of this group had leukemia and the adult, eosinophilic granuloma.

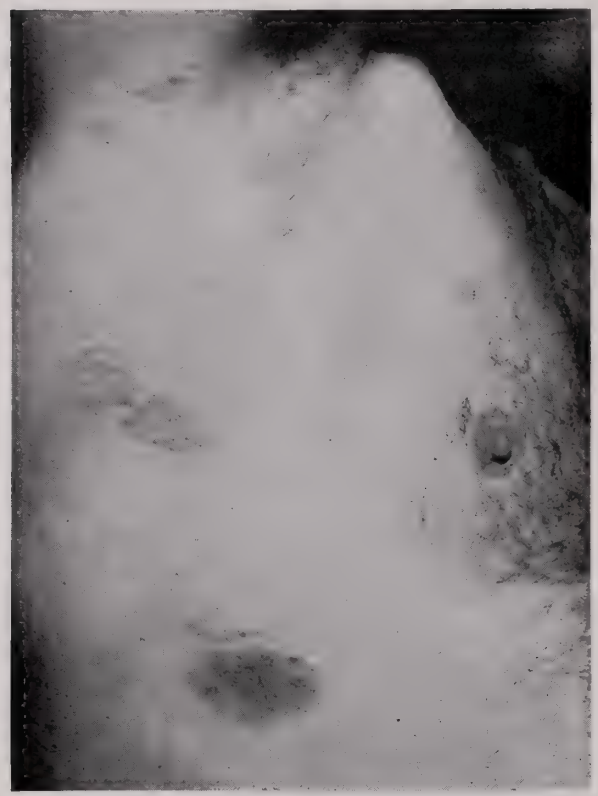

Fig. 3—This patient originally had alopecia mucinosa; later reticulum cell sarcoma developed. Note the two types of lesions, follicular papules and the erythematous plaque-form, in the same patient.

Fig. 4—Erythematous, somewhat indurated, plaques on extensors of forearms and abdomen that were associated with hair loss characterize the lesions of alopecia mucinosa in this patient.

Because 50% of the patients with generalized plane xanthoma later have systemic disease, the physician should search for multiple myeloma or leukemia in patients with these cutaneous lesions. This is particularly true when the patient is an adult, has normal blood lipids, and has no history or findings that relate his present skin findings with other xanthomatous disease.

Alopecia Mucinosa

Since 1957, alopecia mucinosa (follicular mucinosis) has been accepted as a clinical entity. Because the histologic changes were recognized as those of mucinous degeneration of the pilosebaceous unit, the name "alopecia mucinosa" was retained for this entity rather than "follicular mucinosa." Subsequently, combined evaluation of reported cases showed that many of these patients had associated lymphoreticular disease; this was particularly true in patients more than 40 years old.

Dermatological Findings

Two types of lesions are seen in alopecia mucinosa. One consists of grouped, flesh-colored to erythematous follicular papules that frequently become hyperkeratotic. This type is most often seen during childhood and represents a benign transitory disease. The second type consists of somewhat indurated, flesh-colored to red plaques, the surface of which may be somewhat scaly. This second type of lesion is most often one of the clinical features in older adults who may have associated lymphoreticular disease. Combinations of these two types of lesions may appear in the same patient (Figure 3).

Loss of hair in the involved area is the most consistent clinical feature (Figure 4). This finding is obvious when the skin lesions of alopecia mucinosa occur on body surfaces where long hair is ordinarily present. The lesions of alopecia mucinosa occur most commonly on the face, neck, trunk, and upper extremities. Local symptoms are usually minimal.

Development of Neoplasia

In 1957 it was suggested that the disease in some patients was of unknown origin and therefore "primary," whereas in others it was secondary or "symptomatic" and associated with another disease, usually reticulosis. Pinkus proposed the possibility of a virus parasitizing the follicular sheath cells as the possible cause of the follicular mucinosis. In those patients in whom the disease is benign, sufficient immunity develops so that the disease remains localized. In others, he believes that the continued stimulation of the endothelial system by the virus gradually leads to the development of lymphoma.

Ten cases of alopecia mucinosa have been studied in detail[5] at the Mayo Clinic. The lesions in two cases clinically resembled mycosis fungoides, and in one case, a histologic transition to mycosis fungoides. In three other cases, in which mycosis fungoides was seen clinically, the follicular mucinosis was considered a secondary histologic change.

Pinkus,[6] in analyzing his own cases, found that 31 of the 60 patients (52%) were more than 30 years of age and that eight of these (25%) eventually had lymphoma. More re-

Fig. 5—(*A*) Distribution of pemphigoid lesions. (*B*) Area shows blisters in bullous pemphigoid.

cently, Plotnick and Abbrecht[7] reviewed the literature and found 90 cases of alopecia mucinosa; 28 of these patients were more than 40 years old. Of this group, four had evidence of mycosis fungoides or lymphoblastoma, an incidence of 15% for this association.

Pemphigoid

A generalized blistering eruption to be differentiated from erythema multiforme, dermatitis herpetiformis, herpes simplex, and herpes zoster, and termed "pemphigoid," may occur in association with a malignant neoplasm, most often lymphoma.

Dermatological Findings

Generalized bullous pemphigoid most often involves older adults, past middle age. It consists of vesicles and bullae that predominantly involve the trunk and proximal portion of the extremities.[8] The blistering may vary from vesicles that are a few millimeters in diameter to large bullae that are several centimeters. Some may arise on an urticarial base and others on apparently normal skin. Frequently, small clusters of vesicles resembling "dewdrops" may form peripherally around erythematous plaques which are sites of previous involvement (Figure 5). Generally there are recurrent crops of lesions.

As many as 25% of the patients may have involvement of the mucosa of the oral cavity and the anogenital region. Intense pruritus and at times a burning sensation accompany the eruption.

Skin biopsy reveals a subepidermal bulla that seems to originate as a response to edema of the upper part of the dermis, elevating the epidermis.

Development of Neoplasia

An early report on pemphigoid stresses the occurrence of this disease in elderly but otherwise healthy adults.[8] Subsequent case reports indicate that generalized blistering eruptions, best classified as pemphigoid, occur with increased frequency in patients with malignant neoplasms. Our own experience would seem to confirm this.

Skog[9] reviewed the problem of the occurrence of malignant tumors in association with vesicular and bullous lesions. From his résumé of cases, it appears that the bullous eruption may have been a consequence of roentgen therapy initiated for the primary disease in three patients. In another three patients, cutaneous eruption heralded the appearance of the carcinoma. In the final three patients, the vesiculobullous eruption occurred when a metastatic disease developed.

Patients with generalized bullous eruptions not readily attributable to another cause should be examined for underlying malignant disease.

Multiple Mucosal Neuromas

As a cutaneous sign, multiple mucosal neuromas should be suggestive of a possible medullary carcinoma of the thyroid, pheochromocytoma, or both. Stimulated by the diagnostic presence of neuromas in the tongue, Gorlin and associates[10] found 17 cases in which multiple mucosal neuromas were associated with carcinoma of the thyroid or pheochromocytoma, or both. In their most recent review of thyroid carcinoma, Woolner and associates[11] noted seven patients who had findings that warranted their inclusion in this group.

Dermatological Findings

The mucosal neuromas are pink, pedunculated nodules that often first involve the tongue and labial tissues. The lips enlarge and become "blubbery" or "negroid" in appearance. In the tongue, the neuromas are characteristically situated at the tip and along the margins. In the patients seen at the Mayo Clinic, these tumors were noted early in life and became larger and more bothersome during adolescence.

The conjunctival mucosa is affected later, and the increasing size of the neuromas causes eversion of the eyelids (Figure 6). This feature, with the labial changes, produces a distinctive and characteristic facies. The buccal, gingival, laryngeal, and nasal mucosae are less frequently affected.

Development of Neoplasia

Medullary carcinoma of the thyroid was noted in seven of the 17 cases reviewed by Gorlin and associates.[10] These authors emphasized that the onset of thyroid carcinoma occurred at an early age but never before the

18th year of life. All the patients in Woolner and associates'[12] series were relatively young, the oldest being 27 years of age. This is in contrast to the high incidence of medullary carcinoma of the thyroid in patients in the sixth and seventh decades of life, when this tumor occurs independent of the other stigmata.

Pheochromocytoma was noted in seven of the 17 cases reported by Gorlin and associates.[10] Among these there was clinical evidence to indicate that this tumor may have been present in an additional three cases. In four of the seven cases the tumors were bilateral. Woolner and associates' unpublished studies[11] show that bilateral pheochromocytoma was present in five of their seven patients.

In their review, Gorlin and associates[10] emphasized the presence of a marfanoid habitus and diverticulosis in some of the patients. Woolner and associates[11] reported two patients, both with ganglioneuromatosis and diverticulosis, and still other patients with hypercalcemia, one of whom had multiple adenomas of the parathyroid gland.

The physician should be aware that firm, flesh-colored tumors of the oral and conjunctival mucosal surfaces may indeed be a clue to underlying carcinoma of the thyroid and, if associated with hypertension, perhaps also to the presence of pheochromocytoma.

Ataxia-Telangiectasia (Louis-Bar Syndrome)

Ataxia-telangiectasia is a familial neurocutaneous syndrome transmitted as an autosomal recessive trait that consists of progressive cerebellar ataxia in association with oculocutaneous telangiectasias. Malignant tumors eventually develop in some of these patients.[13,14]

Dermatological Findings

The disease has its onset early in life and is frequently first noted because of defects in station and gait as the child tries to walk. Mild spontaneous athetoid movements begin early, particularly in the upper extremities, and there is progression of these symptoms with advancing age. Patients assume characteristic postures even when sitting. Dysergia and intention tremor may develop.

The telangiectasias of the conjunctivae and skin usually appear somewhat later, although these changes have been reported to occur in children as young as two years old. The onset of these changes is more frequently delayed until the age of four to six. The bulbar conjunctivae are involved initially, with subsequent telangiectasias developing on the face, neck, and ears. The cubital and popliteal fossae may also be involved.

Clinical Manifestations

As the disease progresses, peculiar eye movements that simulate ophthalmoplegia develop. Frequent sinopulmonary infections including bronchiectasis commonly occur, and clubbing of the fingers and toes may develop. Afflicted children are often retarded in growth although their intelligence is normal. Their intelligence quotient tends to decrease on serial testing, as such tests, depending on visual coordination, become correspondingly more difficult as

Fig. 6—(*A*) Fibromas of eyelids and edema of lips which present a characteristic facies. (*B*) In this syndrome, fibromas of tongue primarily involve anterior portion.

the ocular symptoms become worse. The speech becomes slowed, slurred, and scanning, and the voice becomes weak and indistinct.

On autopsy study, the brain shows cerebellar atrophy with primary chronic, diffuse cortical degeneration.[13] Decreased numbers of Purkinje and granular cells, and to a lesser extent basket cells, are seen in the brain substance. The spinal cord is apparently not changed. Enlargement of the venules in the cerebellar leptomeninges cannot at this time be definitely related to the oculocutaneous telangiectasias. The presence then of this peculiar ataxic state, together with the oculocutaneous telangiectasias, makes the diagnosis of this condition relatively easy.

Development of Neoplasia

A number of authors have stressed the immunologic defects in these patients. Peterson and associates[15] summarized the incidence of cancer in ataxia telangiectasia and noted that of 125 patients whose cases they reviewed, two had Hodgkin's disease, four reticulum cell sarcoma, two small-cell sarcoma, and one bilateral dysgerminoma.* These authors suggested that the reticulum cell hyperplasia and the malignant neoplasms that develop in these patients may be related to the abnormal thymus.

Reed and colleagues,[14] in reporting on 22 patients in 15 family histories, revealed that many members of these families gave a history of cancer of all types, including lymphosarcoma and leukemia, in addition to diabetes mellitus and tuberculosis.

*See Test Your Word Score Page 1757.

Summary

This presentation describes the cutaneous findings in a group of relatively uncommon syndromes. We hope to challenge the clinician to critically evaluate any skin changes in patients and to consider the possibility that they may be related to a systemic disease. In the conditions enumerated, the skin changes are distinctive and should prompt the physician to suspect that a visceral cancer may be present.

Cryptococcosis Presenting as an Osteolytic Rib Lesion

JAFER KUAITY, M.D.*
F. BRUCE LEWIS, M.D.†
Minneapolis, Minnesota

Cryptococcosis, a chronic fungal disease, usually appears in an asymptomatic pulmonary form. When dissemination occurs, it is most frequently in the central nervous system, although other sites of involvement have been reported. The purpose of this report is to present a patient, who, on routine chest x-ray, was found to have an osteolytic rib lesion. She was otherwise completely asymptomatic and initially had no evidence of disease in any other site. On surgical biopsy the rib lesion was found to be due to cryptococcosis.

Case Report

This 46-year-old negro female was admitted to Mount Sinai Hospital on January 17, 1967, for investigation of an osteolytic rib lesion found on routine pre-employment chest x-ray.

Past History and Findings

The patient was first seen at this hospital in 1959 because of a persistent nodule in the left upper eyelid. She was otherwise asymptomatic, and physical examination at that time was normal. Biopsy of the eyelid nodule revealed a noncaseating granuloma consisting of epithelial cells, giant cells and lymphocytes. No further workup was done, and the patient was discharged without therapy with a tentative diagnosis of sarcoidosis.

In 1962 she had a recurrence of the eyelid nodule. At this time she was found to have cervical, axillary, epitrochlear and inguinal lymphadenopathy. The nodes were firm, smooth and nontender, varying in diameter between 3 and 5 cm. Examination of the lungs and heart was normal. Palpation of the abdomen revealed moderate hepatosplenomegaly.

Skin tests for tuberculosis, histoplasmosis, coccidioidomycosis and blastomycosis were negative. Sputum cultures for acid-fast bacilli and fungi were negative, as were blood cultures and complement fixation tests for fungi. A chest x-ray showed right paratracheal node enlargement but was otherwise negative. Cervical lymph-node biopsy showed non-caseating granulomas (Figure 1) similar to those seen originally in the eyelid nodule. Biopsy of a Kveim test (Figure 2) was considered con-

Fig. 1—Cervical lymph node biopsy (170X) showing non-caseating granulomas.

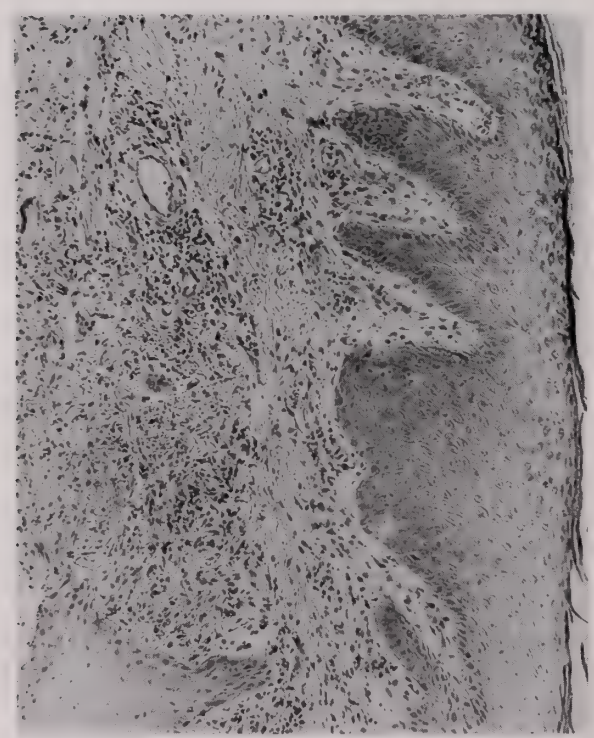

Fig. 2—Skin biopsy of the Kveim test (170X) showing non-caseating granulomas.

sistent with a diagnosis of sarcoidosis.

Present History and Findings

From 1962 until her most recent admission in 1967, the patient was entirely well. At no time did she receive steroids or other therapy. She applied for a new job in December 1966, and at that time was found to have osteolytic areas in the left third rib.

On admission the patient appeared vigorous and healthy. She was afebrile. She was again noted to have cervical, axillary, and inguinal lymph-node enlargement which did not seem to have changed since her previous admission. Examination of the lungs, heart and abdomen was otherwise negative. Chest x-rays showed at least one osteolytic lesion in the left third rib posterolaterally (Figures 3 and 4), but x-rays of the skull, clavicles, spine, hands, feet and pelvis were all negative.

Laboratory Examinations

Urinalysis negative. Hemoglobin 12.2 mg %; hematocrit 36%; RBC 3.8 million; WBC 8,870. Polys 86, lymphocytes 10, monocytes 3, eosinophils 1, basophils 0. BUN 18. Blood glucose 90 mg%. Serum electrolytes normal. Serum calcium 10 mg% and phosphorus 4 mg%. Total protein 8 gm% with albumin of 4.5 gm%. SGOT 10 units. Sedimentation rate 50 mm/hr. Serum creatinine 0.7 mg%.

A partial excisional biopsy of the involved rib was performed. Microscopic examination of this material showed a non-caseating granuloma (Figure 5), characterized by lymphocytes, histiocytes, and giant cell infiltration with PAS-positive intracellular microorganisms. Cultures of this organism were performed in three laboratories,* and the unanimous conclusion was that the organism was Cryptococcus neoformans. After surgery, sputum cultures were obtained; these also grew out fungi which on further cultural and inoculation studies had the characteristics of Cryptococcus neoformans.

Skin tests for tuberculosis, and skin and complement fixation tests for histoplasmosis, blastomycosis and coccidioidomycosis were negative. Attempts to isolate Cryptococcus from blood and urine were unsuccessful. The cerebrospinal fluid examination for electrolytes, sugar, proteins and cells was within normal limits, and also failed to grow out any organism.

The patient was considered to have disseminated cryptococcosis because of the pulmonary and rib involvement, and she was treated with Amphotericin B. After administration of 1.5 grams intravenously, the sputum cultures were negative, and involvement in the rib lesion decreased in subsequent x-ray examinations. The previously biopsied eyelid and lymph node were reviewed and re-examined for fungus, but none could be found.

Discussion

Disseminated cryptococcosis usually involves the central nervous system and is generally symptomatic. Bone involvement, which occurs

*Mount Sinai Hospital; at Minneapolis Veteran's Administrative Hospital, Dr. Wendell Hall; and Duke University, Durham, North Carolina, Dr. Norman F. Conant.

in about 10 percent of the cases, is most often characterized by involvement of the long bones with pain, swelling and a slowly progressive course suggestive of chronic osteomyelitis. Our patient was unusual in that she had no evidence of illness except the initial asymptomatic lytic lesion in the rib. Subsequent sputum cultures were positive for Cryptococcus, but the exact origin of these organisms is difficult to determine. There was no evidence of parenchymal involvement on chest x-ray. Conceivably the Cryptococcus could have been released secondary to the surgery, or perhaps the patient had a cryptococcal bronchitis. We have no proof of the site of involvement.

In 1894 Benham cited Busse, who described the first case of cryptococcosis in a 31-year-old woman with a granulomatous lesion of the tibia which subsequently grew out the organism.[1] The bony lesions caused by Cryptococcus neoformans are usually osteolytic with slight periosteal reaction.[2] Nearly every bone has been found to be involved in the various cases reported in the literature, but there appears to be a predilection for bony prominences, cranial bones and vertebrae.[3]

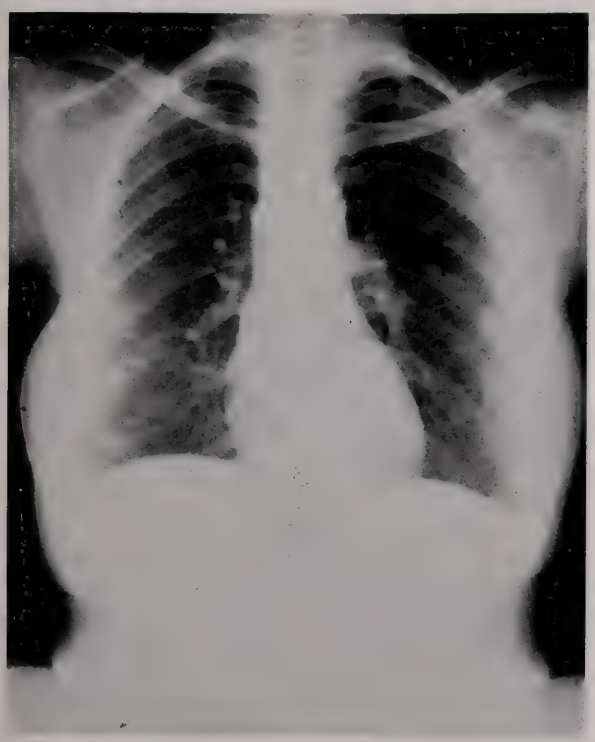

Fig. 3—Posteroanterior view of chest x-ray on admission. The arrow indicates the osteolytic lesion.

Cryptococcosis involving the ribs has rarely been described. Gosling et al.,[4] in their review of the literature of skeletal cryptococcosis, cited one case with involvement of the 10th rib reported by Dienst. Dormer et al.[5] reported a case of disseminated cryptococcosis with 9th rib involvement but with multiple bone lesions in other areas. Cryptococci may also involve the bones locally without dissemination. Our patient had isolated involvement of only one

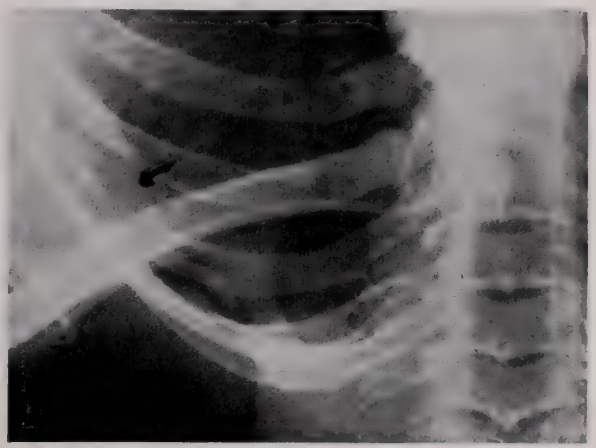

Fig. 4—Closer view of the left third rib. The arrow indicates the lesion.

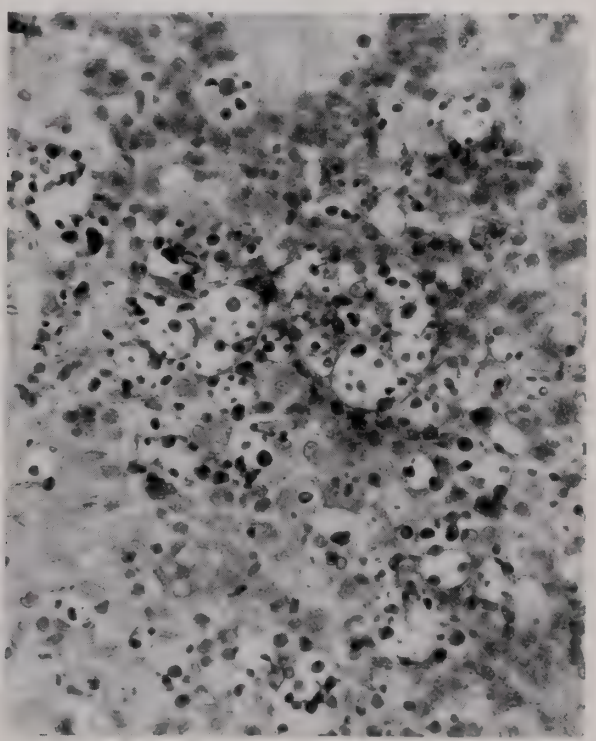

Fig. 5—Partial excisional biopsy of the third rib (periodic acid Schiff stain (450X)) showing the rounded intracellular microorganisms which have the cultural characteristics of Cryptococcus neoformans.

rib, without any evidence of bone involvement elsewhere. The only other manifestation of her cryptococcosis was positive sputum cultures obtained after surgery.

Cryptococcosis has been reported in patients with pre-existing tuberculosis,[7,8,9] leukemia,[10] other malignant diseases of the reticuloendothelial system,[11,12,13,14,22] diabetes,[15,16] and also as a complication of steroid therapy.[17,18,19] In a recent review by Harris et al. regarding the association of cryptococcosis and sarcoidosis, 11 such cases were found and an additional case was documented.[20] Symmers in 1967 mentioned five unpublished personal cases of cryptococcosis which manifested itself in the setting of sarcoidosis. Although our patient had a previous diagnosis of sarcoidosis, it is of interest that the course was an extremely indolent one and was never thought to require any form of therapy, including steroids.

Geraci[23] stated that the following are indications for treatment of cryptococcosis with Amphotericin B:

1. Progressive, diffuse, acute, subacute, chronic pneumonic, bronchopneumonic, cavitary or miliary disease, with or without pulmonary symptoms, and with positive cultures of sputum or bronchial secretion.
2. Infections associated with systemic diseases or cryptococcal infection of the central nervous system.
3. Doubtful cases in which the central nervous system shows some changes but the cultures are negative.

We elected to treat this asymptomatic disease with Amphotericin B because of the underlying systemic disease, the evidence for dissemination as manifested by the positive sputum culture, and the theoretical risk of central nervous system involvement. Our patient's sputum culture after treatment became negative, and there was improvement in the roentgenological picture of the rib lesion. She had no toxicity from the treatment and on continued follow-up has remained asymptomatic. There is no new evidence of cryptococcosis.

Summary

A patient with a long-standing diagnosis of sarcoidosis was found on routine chest film to have an osteolytic rib lesion which on biopsy proved to be due to Cryptococcus neoformans. Treatment with Amphotericin B appeared to improve the condition.

Animal Circle

Since seven of the twelve constellations on the ecliptic represented animals, the ancients called the ecliptic the zodiac, from the Greek zodiakos (animal plus circle).

Money talks and most of us never get bored listening.—Herbert Prochnow

Multiple Endocrine Adenomatosis

JOHN P. DELANEY, M.D.*
MAYNARD E. JACOBSON, M.D.
Minneapolis, Minnesota

MULTIPLE ENDOCRINE ADENOMATOSIS is a syndrome characterized by: (1) tumors or hyperplasia of the endocrine glands, particularly parathyroid, pancreas, pituitary, and adrenal, (2) a very high incidence of associated peptic ulcer, (3) familial occurrence.

In their extensive review Ballard, Frame, and Hartsock[1] found that the multiple endocrine adenomatosis-peptic ulcer complex had been reported in 11 families up to 1962. Many of the individual case histories which they reviewed did not, however, provide adequate information regarding kindred. The present report documents an additional family exhibiting multiple endocrine adenomatosis. Noted here for possibly the first time is relief of the peptic ulcer diathesis† following surgical correction of the hyperparathyroid aspect of the syndrome.

Case Report

In June 1966 a 59-year-old white female was admitted for the 15th time to the University of Minnesota Hospitals, complaining of typical peptic ulcer symptoms.

Ulcer History

Her ulcer history, which dated back to 1938, included a number of upper gastrointestinal bleeding episodes and occasional spells of vomiting. In 1952 she had a 138-gram tubular resection of the stomach. Ulcer symptoms persisted following this operation and an active duodenal ulcer crater was demonstrated later in 1952, in 1953, and again in 1957. An additional segmental gastrectomy with a complementary pyloroplasty was done in 1957. At this time a 2.5-cm. round nodule removed from the hilum of the spleen proved on histologic section to be a pancreatic islet cell adenoma. During succeeding years the patient continued to complain of epigastric distress which was, however, somewhat less severe and less frequent than it had been prior to gastrectomy.

In 1964 an upper gastrointestinal x-ray examination showed a recurrent duodenal ulcer. In January 1965 she underwent gastric freezing. Following this treatment the ulcer healed with complete relief of symptoms for approximately 16 months. In April of 1966 symptoms recurred and two gastric ulcers were seen on both barium examination and gastroscopy. One of the ulcers measured

3 cm. in diameter and was located on the lesser curvature; the other, on the greater curvature, was approximately 1 cm. in diameter. These lesions persisted unchanged through June of 1966 in spite of rigorous medical management.

Family History

At this time the patient was first investigated for possible hyperparathyroidism. Her family history was as follows. Her father died at age 36 of upper gastrointestinal hemorrhage. A sister died at age 40 after a five-year history of ulcer disease and recurrent renal lithiasis. At postmortem examination this sister was reported to have a malignant tumor, probably originating in the pancreas. A living 62-year-old sister has mild diabetes mellitus and a long history of complicated ulcer disease which was relieved by a partial gastrectomy. On a single examination her serum calcium was 11.9 and serum phosphorus 2.0. Although she probably has hyperparathyroidism she is symptom-free and has declined operative therapy. A 32-year-old daughter has had recurrent symptoms and x-ray evidence of duodenal ulcer. Her serum calcium was 10.4 and serum phosphorus 1.9. She also has presumptive hyperparathyroidism but has permitted no further workup. Three other daughters and three brothers have exhibited no features of the multiple endocrine adenomatosis syndrome. The grandparents of this patient had no history suggestive of multiple endocrine adenomatosis. Her grandchildren are still too young to manifest the syndrome.

Laboratory Studies

Laboratory data on the patient include numerous gastric analyses between 1952 and 1966. The highest acid secretory value obtained was 18.6 mEq. of free acid in a 12-hour overnight aspiration of 1959, which is within normal limits. In 1964 a one-hour aspiration of the unstimulated stomach yielded no free acid and an eight-hour overnight aspiration provided 2.1 mEq. of free acid. Thus, although the patient had a proven pancreatic islet cell adenoma, none of the values for gastric acidity were in a range consistent with the Zollinger-Ellison syndrome. Repeated serum calcium levels ranged from 10.3 to 11.5 mg. %, serum phosphorus from 2.1 to 2.3 mg. %. Standard clearance of creatinine was 133 liters/24 hours. Tubular reabsorption of phosphorus was 83% (normal being over 85%) on a regular diet, 66% on a Bauer Aub diet. Serum alkaline phosphatase was 23 King Armstrong Units (normal less than 14 units). Skeletal x-ray examination revealed demineralization of the spine and subperiosteal reabsorption of bone in the phalanges, interpreted as characteristic of hyperparathyroidism.

Parathyroid Glands

In June of 1966 the neck was explored through a collar incision. Three of the four parathyroid glands were grossly enlarged and brownish in color and were excised. The largest weighed 4 gm. and measured 3.2 x 1.4 x 1.2 cm. Approximately half of the normal-sized fourth gland was also removed and sent to the pathologist. On histologic examination all four glands were interpreted as showing diffuse hyperplasia with loss of fat and chief cells, oxyphil cells and water-clear cells arranged in a pattern suggestive of nodular hyperplasia. No normal parathyroid tissue was identified in any of the specimens.

Following parathyroidectomy the serum calcium fell as low as 7.1 mg. % on the sixth postoperative day. The serum phosphorus at this time was 2.1 mg. %. The patient complained of some paresthesias in the limbs but was satisfactorily maintained on oral calcium and vitamin D supplements. She has continued to run a somewhat depressed serum calcium level, the last being 8.9 mg. % with a 4.2 mg. % serum phosphorus. When she neglects to take calcium supplements, limb paresthesias and circumoral numbness develop.

Ulcer symptoms disappeared immediately following surgical relief of hyperparathyroidism. Two months postoperatively the gastric ulcers had healed completely, as evidenced by both x-ray and gastroscopic examinations. During this period the patient had not followed dietary restrictions or had other medical treatment. Gastrointestinal symptoms have not recurred in the 28 months since surgical correction of the hyperparathyroidism.

This patient and her family illustrate many of the important features of the multiple endocrine adenomatosis syndrome.

Multiglandular Involvement

By definition, more than one of the endocrine glands are involved in the disease process. In addition, in any single endocrine tissue there are characteristically multiple adenomas, particularly parathyroid or pancreas. Ballard and colleagues[1] noted parathyroid adenomas in 88% of the cases reviewed and pancreatic adenomas in 81%. Also frequently involved, but not detected in this family, are pituitary (65%), adrenal (38%) and thyroid (19%) lesions.

Peptic Ulcer

Peptic ulcer has been reported in 57% of the individual cases of multiple endocrine adenomatosis. The ulcers are often multiple and atypical in locations. Characteristically the symptoms are resistant to conventional medical management and the disease is marked by frequent complications. Approximately 20% of patients with multiple endocrine adenomatosis also have the Zollinger-Ellison syndrome: ulcer disease associated with pancreatic nonbeta islet cell tumors and marked gastric hypersecretion of acid. Our patient did not have particularly high acid outputs but did have an islet cell tumor. Ulcer symptoms are the most frequent presenting complaints of patients with the multiple endocrine adenomatosis syndrome, and complications, particulary perforation, are the most com-

mon cause of death. Any patient with a strong family history of ulcer disease or marked hypersecretion of acid from the stomach should be screened for the possibility of multiple endocrine adenomatosis.

Pancreatic Pathology

Eighty-one percent of the reported patients with multiple endocrine adenomatosis had adenomas of the pancreas, usually multicentric.[1] Approximately 30% had demonstrated hypoglycemia associated with beta cell adenomas. Two thirds of patients with pancreatic lesions had nonbeta cell tumors, 25% carcinoma, 32% multiple adenomas, and 7% solitary adenoma.

Parathyroid Pathology

Parathyroid involvement in multiple endocrine adenomatosis is to be contrasted to that found in patients with primary hyperparathyroidism. Multiple parathyroid glandular involvement is the rule (68%) in multiple endocrine adenomatosis and the exception (16%) in primary hyperparathyroidism. While the majority of the multiple lesions have been called adenomas, they most probably represent diffuse hyperplasia of the parathyroid glands as described by Cope et al. in 1958,[2] rather than true adenomas. The histologic distinction between hyperplasia and adenoma depends upon finding a rim of normal parathyroid tissue with the adenoma. Our patient demonstrated hyperplastic cellular organization suggesting nodular hyperplasia.

Pituitary Pathology

Ballard and colleagues noted that pituitary adenomas were documented in 55 of their collected series of 85 patients. Almost half of these were chromophobe* adenomas. Eosinophilic hyperplasia or adenomas were associated with acromegaly in about a quarter of the patients with pituitary lesions.

Genetic Features of Multiple Endocrine Adenomatosis

Wermer, in 1954,[3] first emphasized the importance of the familial occurrence of this syndrome. He postulated that the trait is carried by a single autosomal dominant gene, which has a high degree of penetrance and expressivity. Pertinent features consistent with this thesis are that affected individuals generally have one affected parent. Approximately half of the offspring of a multiple endocrine adenomatosis parent manifest the syndrome. Normal offspring of a parent with this syndrome do not carry the trait and therefore have normal children.

Discussion

As noted above, the most frequent presenting complaint of patients with multiple endocrine adenomatosis is secondary to peptic ulcer disease. It is probably not practical to screen all patients with ulcer for hyperparathyroidism, but certainly those with a strong family history, intractable disease, extreme hyperacidity, or patient or family history of renal stones should be carefully investigated for the possibility of concurrent hyperparathyroidism and for other endocrine tumors. In addition, a patient or family history of hypoglycemic attacks, acromegaly, adrenal or thyroid adenomas should also suggest the possibility of this syndrome. Primary hyperparathyroidism is allegedly associated with an increased incidence of peptic ulcer disease. Characteristically these ulcers are chronic, recurrent, and recalcitrant to medical management.

Wilder and colleagues,[5] reviewing this association, concluded that the great majority of patients obtain definite relief from the ulcer diathesis following parathyroid surgery. This has apparently not been the case with multiple endocrine adenomatoses and ulcer disease. Wermer[4] suggested that the ulcer is an independent manifestation of the syndrome rather than secondary to hyperparathyroidism. If his contention is correct, one would anticipate that relief of hyperparathyroidism would not alleviate the ulcer diathesis. The patient reported in this paper experienced healing of ulcers and definite disappearance of symptoms for approximately two years following relief of hyperparathyroidism. We would therefore conclude that correction of hyperparathyroidism may provide relief of ulcer symptoms in patients with multiple endocrine adenomatosis.

*See Test Your Word Score Page 1757.

Summary

Multiple endocrine adenomatosis is a syndrome characterized by multiple tumors of the endocrine tissues and a high incidence of peptic ulcer. A family is reported which exhibits many of the features of this syndrome, including hyperparathyroidism, ulcer disease, and pancreatic tumors. The patient presented was completely relieved of ulcer symptoms by surgical correction of hyperparathyroidism.

London Doctors

Your modern London doctor has many advantages denied to his predecessors. There is the National Health Service, which is going to be quite wonderful if once we can get over the first twenty years of teething troubles. . . . There are medical films and medical films. The former for teaching purposes and the latter for the greater glory of Wardour Street and the benefit of the box office.

London has wonder-drugs and wonder-machines often big enough and bright enough to obscure completely the patients they are intended to benefit. It has medical schools and teaching hospitals which are among the wonders of the world and it has some out-patient waiting-rooms that would have made Rowlandson blench.

There are in London some clinics that have attracted distinguished doctors from all over the world. Just around the corner from one of them and masquerading under a medical title is one of those places where brides-to-be can have all the exercise and massage needed to take their hips down a little.

Wherever you go in London you meet doctors. Wherever doctors go they meet other doctors. At their medical societies, in hospitals, in clubs, and all over the place doctors disagree profoundly about almost everything. There is only one thing they have in common. For forty-nine different reasons they would all rather live and work in London than anywhere else in the world.*

Blood Gas Monitoring of Patients in Respiratory Failure

DAVID E. DINES, M.D.*
WILLIAM W. DOUGLAS, M.D.*
EDWARD C. ROSENOW, III, M.D.*
Rochester, Minnesota

THE INTERRELATIONSHIP of ventilatory function, carbon dioxide tension (P_{CO_2}), oxygen tension (P_{O_2}), and hydrogen ion concentration ($[H^+]$) must be appraised in each clinical situation in which there is alveolar hypoventilation with associated respiratory acidosis. Impairment of ventilation can produce respiratory acidosis with superimposed metabolic alkalosis or metabolic acidosis. Appropriate treatment of respiratory failure requires an awareness of the mechanism producing the ventilatory impairment and reasonable quantitation of the resulting chemical abnormalities in the blood. As treatment proceeds, these chemical derangements can change quickly, so that frequent reappraisal is required. Compensatory changes complicate the problem.

The basic concepts in the physiology of respiratory acidosis can be understood better if considered in the form of equations.

Ventilation Equation

$$P_{aCO_2} = 0.864 \frac{\dot{V}_{CO_2}}{\dot{V}_A}. \qquad \text{(equation 1)}$$

The arterial CO_2 tension (P_{aCO_2}) depends on the quotient of the rate of metabolic production of carbon dioxide ($\dot{V}_{CO_2}$) divided by the rate of removal of carbon dioxide from the blood by the lungs as measured by the rate of alveolar ventilation ($\dot{V}_A$ = total ventilation minus dead space). The metabolic production of carbon dioxide increases in relation to rest in some conditions (such as exercise, fever, and hyperthyroidism) and decreases in others such as hypothyroidism. Hypoventilation and hyperventilation are defined on the basis of the resulting P_{aCO_2}, so that by monitoring this parameter we can determine if alveolar ventilation is appropriate to clear the CO_2 being produced by the body's metabolic processes.

*Mayo Clinic and Mayo Foundation: Section of Medicine.

Acid-Base Equation

The hydrogen ion concentration in plasma is given by:

$$[H^+] = 24 \times \frac{P_{CO_2}\ \text{(Lungs)}}{[HCO^-_3]\ \text{(Kidney)}}. \qquad \text{(equation 2)}$$

The acid-base equation pertains to the regulation of acid-base balance and is a simplified form of the Henderson-Hasselbalch equation. It can be thought of as:

$$pH = \frac{[HCO^-_3]\ \text{(renal regulation)}}{H_2O + CO_2\ \text{(ventilatory regulation)}}.$$

The numerical constant used in the acid-base equation is appropriate for blood plasma[1] when hydrogen ion concentration ($[H^+]$) is measured in nanoequivalents (equivalents per liter $\times 10^{-9}$), bicarbonate ion concentration ($[HCO^-_3]$) in milliequivalents per liter, and carbon dioxide tension in millimeters of mercury. Dissolved carbon dioxide combines with water to form carbonic acid. Thus, if effective alveolar ventilation is reduced and carbon dioxide tension (P_{ACO_2}) increases, the hydrogen ion concentration will increase but the bicarbonate concentration in the plasma will remain constant. However, if the carbon dioxide tension remains increased, the kidneys will compensate by retaining bicarbonate. If the carbon dioxide tension and bicarbonate concentration increase proportionately, the hydrogen ion concentration will be normal even though the carbon dioxide tension is high; this is compensated respiratory acidosis. In chronic obstructive pulmonary disease, carbon dioxide tension can increase faster than compensation can be achieved through renal adjustment; thus the hydrogen ion concentration increases (pH decreases) and respiratory acidosis is produced.

Oxygenation Equation

The third equation (the alveolar gas equation) deals with the alveolar oxygen tension (P_{AO_2}):

$$P_{AO_2} = P_{IO_2} - P_{ACO_2}\left(F_{IO_2} + \frac{1 - F_{IO_2}}{RQ}\right), \qquad \text{(equation 3)}$$

in which P_{AO_2} = alveolar P_{O_2} (mm Hg); P_{IO_2} = P_{O_2} of inspired air (mm Hg); P_{ACO_2} = alveolar P_{CO_2} (mm Hg); F_{IO_2} = fraction (%) of O_2 in inspired air; and RQ = respiratory exchange ratio. The respiratory exchange ratio (RQ) is the ratio between metabolic output of CO_2 and metabolic uptake of O_2 and varies between 0.7 and 1.0. Usually, the RQ is less than 1.0 in the steady state.[2,3]

$$RQ = \frac{\dot{V}_{CO_2}}{\dot{V}_{O_2}}. \qquad \text{(equation 3a)}$$

If R = 1, then $P_{AO_2} = P_{IO_2} - P_{ACO_2}$.

More simply, the oxygenation equation states:

Arterial oxygen tension (P_{aO_2}) = inspired air P_{O_2} minus alveolar P_{CO_2}. In respiratory acidosis with CO_2 retention, the partial pressure of oxygen in the alveoli may be significantly reduced as shown by the relationship in the following example:

Normal: P_{AO_2} (110 mm Hg) = P_{IO_2} (150 mm Hg) − P_{ACO_2} (40 mm Hg).

Respiratory acidosis: P_{AO_2} (60 mm Hg) = P_{IO_2} (150 mm Hg) − P_{ACO_2} (90 mm Hg).

The latter relationship demonstrates why there is a decrease in alveolar oxygen tension when there is an increase in the arterial carbon dioxide tension.

Pulmonary Alveolar-Arterial Oxygen Gradient

The net pulmonary alveolar-arterial oxygen gradient is the difference between the alveolar and arterial oxygen tensions. This gradient is several millimeters of mercury greater than would be anticipated. The gradient exists as a result of diffusion limitation in the alveolar membrane and shunting of deoxygenated blood to the left heart by way of underventilated alveoli or via bronchial veins. The partial pressure in the alveolus (P_{ACO_2}) is equal to the partial pressure in arterial blood (P_{aCO_2}) because there is no significant diffusion gradient of carbon dioxide. Thus, as shown in the preceding paragraph, it becomes possible to calculate average alveolar oxygen tension from a knowledge of the oxygen tension in the inspired air, the respiratory quotient, and the arterial carbon dioxide tension.

How can we obtain meaningful information in critically ill patients with respiratory failure? Alveolar samples are difficult to collect

in patients requiring assisted ventilation, and our data are derived either from the Astrup determination which utilizes arterialized capillary or venous blood or from direct measurements of arterial blood by the use of pH, P_{CO_2}, and P_{O_2} electrodes. Fortunately, the P_{CO_2} in the alveolar gas is the same as the arterial P_{CO_2}, since no significant diffusion gradient exists for carbon dioxide. Thus, given the value for alveolar P_{CO_2} and the oxygen tension of inspired air (150 mm Hg) and being able to estimate the RQ, we can estimate the expected alveolar P_{O_2}. It should be noted that marked discrepancies between the expected values and the measured values are usually due to changes in the physiologic dead space.

The Astrup technique[4,5] was cleverly devised to estimate the carbon dioxide tension of the blood from readings with a pH meter only. It is accurate for measuring pH and P_{CO_2} if blood is drawn, stored, and analyzed properly. If the determination is made on venous blood from a patient who is critically ill with low cardiac output or metabolic acidosis, the results may lead to serious error. It is important to note that this technique gives no information regarding the state of oxygenation of the blood. Hypoxia for any reason, such as alveolar hypoventilation or conditions giving rise to an abnormal alveolar-arterial oxygen gradient, requires direct measurements of the arterial oxygen tension, carbon dioxide tension, and pH for proper assessment.

Normally, the respiratory center is very sensitive to changes in arterial carbon dioxide tension. However, when the arterial carbon dioxide tension increases to a value (variable with each person) greater than 65 mm Hg, the respiratory center becomes less sensitive to carbon dioxide. As a result, hypoxia may become the main stimulus to respiration, through aortic and carotid chemoreceptors. When a patient with chronic obstructive pulmonary disease is given oxygen in a sufficient concentration to increase the arterial oxygen concentration, the stimulus is removed. As a consequence, ventilation and the rate of elimination of carbon dioxide decrease (Equation 1). Then, carbon dioxide concentration increases in the blood, the carbonic acid concentration increases, the hydrogen ion concentration increases (Equation 2), the pH decreases, respiratory acidosis becomes more profound, and coma and death may occur. This situation shows clearly the interrelationships of the three equations and the impossibility of altering one without affecting the other two. Oxygen can be given to increase the oxygen tension if the patient is being adequately ventilated or if he is stimulated to breathe more deeply. This type of acidosis will disappear if the patient blows off the carbon dioxide. Treatment with bicarbonate or tris-(hydroxymethyl)-aminomethane (THAM) may then be deferred unless the pH remains dangerously low (less than 7.20) as the carbon dioxide tension approaches normal.

The three equations are helpful in understanding the alterations in acid-base balance which can lead to derangements in respiration and circulation. Increased airway resistance requires increased respiratory work to maintain the same level of alveolar ventilation, and results in increased metabolic production of carbon dioxide. A decrease in pH leads to pulmonary arterial vasoconstriction (pulmonary hypertension) and further sensitizes the lung to the vasoconstriction caused by hypoxia.[6-8]

The interrelationships of ventilation, carbon dioxide tension, oxygen tension, and hydrogen ion concentration are illustrated by the following seven cases (three of chronic obstructive pulmonary disease, three of diffusion abnormalities, and one of primary alveolar hypoventilation).

Case Reports

Case 1.

A 52-year-old farmer was examined because of shortness of breath of six years' duration; he had been unable to work for two years. He had smoked cigarettes (one pack daily) for 30 years.

On examination he had marked hyper-resonance with absence of breath sounds over the upper part of the thorax and grade 4 (on the basis of 0 to 4) expiratory slowing. A clinical diagnosis of chronic obstructive pulmonary disease with marked bullous disease was made.

A thoracic roentgenogram showed severe bullous emphysema with blebs and marked compression of the lower lobes. A lung scan confirmed the absence of perfusion except in the lower lobes. A pulmonary angiogram confirmed the compression of vasculature from the large bullous sacs. An electrocardiogram was normal.

Pulmonary function studies demonstrated a severe obstructive pattern: maximal breathing capacity, 33 liters/min; maximal midexpiratory flow rate, 0.2 liter/sec; and

nitrogen washout index, 7.7%. The oxygen saturation decreased from 98 to 91% after five minutes of exercise. The carbon monoxide diffusing capacity was 11 ml/min/mm Hg (normal for the patient was estimated to be 22 to 32 ml/min/mm Hg).

Results of arterial gas studies and an Astrup determination[4,5,9] are shown in the Table.

Comment

In Case 1 there was chronic obstructive pulmonary disease due to marked compression of remaining lung tissue by huge bullous areas. Blood was being shunted (alveoli poorly ventilated but adequately perfused), accounting for the low arterial oxygen tension. An operation was performed to resect the huge pneumatocele and relieve the compression of the left lower lobe and the problem of poor alveolar ventilation expressed functionally as pulmonary arteriovenous admixture.

Case 2.

A 52-year-old man was admitted because of shortness of breath and edema of six months' duration. He had smoked for 35 years and had a long history of chronic cough and sputum production. The diagnosis was chronic obstructive pulmonary disease with chronic bronchitis, cor pulmonale, and congestive heart failure. He had hypercapnia, hypoxemia, and polycythemia on admission. An electrocardiogram showed right axis deviation. A thoracic roentgenogram revealed cardiomegaly, pulmonary congestion, and a right pleural effusion. On thoracentesis, 1,300 ml of fluid was removed from the right side. Blood gas and Astrup values are listed in the Table.

Case 3.

A 49-year-old man was transferred here from another hospital; he had marked shortness of breath, chronic cough and sputum production, and profound congestive heart failure. He was hypoxemic, hypercapneic, and polycythemic on admission. A thoracic roentgenogram showed marked pulmonary vascular congestion, cardiac enlargement, pulmonary fibrosis, and bilateral pleural effusions. An electrocardiogram showed a right axis deviation, a prominent P wave in lead V_1, and right ventricular hypertrophy. Pulmonary function studies one year earlier had shown a marked obstructive pattern: maximal breathing capacity, 17 liters/min, maximal midexpiratory flow rate, 0.3 liter/sec, and nitrogen washout index, 17%. Blood gas and Astrup values are listed in the Table.

Comment

Cases 2 and 3 are examples of chronic obstructive pulmonary disease with chronic bronchitis. With infection and secretions obstructing the distal bronchi, areas of lung are being perfused but not adequately ventilated and shunting is occurring, accounting for low arterial oxygen tensions. In both cases the patients had been taking thiazide diuretics and both had low potassium and chloride values, resulting in a metabolic alkalosis superimposed on a chronic respiratory acidosis. Therapy was aimed at improving alveolar ventilation with intermittent positive-pressure breathing, decreasing airway obstruction with bronchodilators, and correcting the hypoxemia with nasal administration of oxygen at 2 liters/min. Potassium chloride was given to correct the electrolyte abnormality.

Case 4.

A 58-year-old woman was admitted to the hospital because of shortness of breath of three months' duration. She had had a right radical mastectomy several years prior to this for grade 3 adenocarcinoma; axillary nodes had been involved and she had been given cobalt treatments postoperatively. She was dyspneic, cyanotic, and hyperventilating. A thoracic roentgenogram showed lymphangial metastases. The diagnosis was diffusion abnormality on the basis of lymphangial carcinomatosis. An electrocardiogram showed a sinus tachycardia. Blood gas and Astrup values are listed in the Table.

Case 5.

A 28-year-old housewife was admitted because of massive gastrointestinal bleeding of three days' duration. An emergency operation was necessary because of inability to keep up with blood replacement over 24 hours. She had a history of Raynaud's disease and dysphagia, and a diagnosis of scleroderma seemed likely on the basis of the appearance of her face and hands. Four days later, she aspirated gastric contents and became markedly cyanotic with acute respiratory distress. We postulated that the profound hypoxemia was related to aspiration pneumonitis superimposed on a diffusion abnormality from pulmonary scleroderma. Blood gas and Astrup values are listed in the Table.

Case 6.

A 60-year-old woman was admitted with marked shortness of breath and rapid heart rate of three months' duration. A left radical mastectomy had been performed for carcinoma of the breast one year before and she had received radiation therapy postoperatively because of involvement of axillary nodes. She had been well until three months prior to this hospitalization. A thoracic roentgenogram showed diffuse lymphangial spread throughout both lung fields. An electrocardiogram showed a sinus tachycardia. Blood gas and Astrup values are listed in the Table.

Comment

Cases 4, 5, and 6 are examples of diffusion abnormalities with arterial hypoxemia and hyperventilation. These three patients likewise had low arterial oxygen tension, indicative of abnormal diffusion; the fact that in Cases 5 and 6 there was no return of arterial oxygen saturation to normal when the patient was breathing 100% oxygen is evidence of abnormal shunting in addition to the abnormal diffusion.

In Cases 4 and 6, oxygen was given by nasal cannula at 5 liters/min to compensate for the alveolar-capillary block. In Case 5, oxygen at 3 liters/min was administered to improve diffusion, but intermittent positive-pressure breathing, expectorants, and induction of coughing also were used to correct the atelectasis that was resulting in areas being perfused but not adequately ventilated.

Case 7.

A 61-year-old obese woman (60 inches, 209 pounds) was admitted with cyanosis, polycythemia, and dyspnea of approximately eight years' duration. She had had numerous phlebotomies during the preceding eight years with only temporary relief of her symptoms. Cyanosis

had been present for approximately four years. The thoracic roentgenogram showed mild cardiac enlargement; the lung fields were clear. Pulmonary function studies revealed mild expiratory slowing. Arterial gas studies showed significant arterial oxygen desaturation and hypercapnia, both of which improved with voluntary hyperventilation of room air (Table).

Comment

Case 7 is an example of alveolar hypoventilation associated with obesity (the Pickwickian syndrome). Ventilatory and diffusion capacities were normal; however, arterial hypercapnia and hypoxia developed, presumably because of failure of the respiratory center to detect these abnormalities. With voluntary hyperventilation, these values returned to normal.

Discussion

The Table compares values from arterial blood gas studies with the Astrup values. In many cases of respiratory failure it is necessary to know oxygen tensions as well and to have more complete information available by direct electrode measurement of the pH and carbon dioxide and oxygen tensions of an arterial blood sample. When there is an arteriovenous fistula, abnormal shunting, or primary alveolar hypoventilation, direct measurements of the arterial oxygen and carbon dioxide tensions should be performed. Comparison of the data demonstrates that, in three of the six cases of abnormal shunting and profound depression of the arterial oxygen tension, monitoring acid-base balance by Astrup determinations would not provide adequate data. Venous carbon dioxide tension is normally about 7 mm Hg higher than arterial carbon dioxide tension.

The Astrup determination indicated a compensated respiratory acidosis in Cases 1, 2, and 3. However, the normal arterial carbon dioxide tension indicated that respiratory failure did not exist but rather that there was a severe respiratory disturbance manifested as arterial hypoxemia. The treatment of the respiratory alkalosis in Case 5 could not be guided by Astrup determinations alone because of the areas of lung being perfused but not ventilated, resulting in the low arterial oxygen tension.

The most important consideration in treatment is the realization of the interrelationships of oxygen tension, carbon dioxide tension, and hydrogen ion concentration in each case of respiratory failure. Direct arterial blood gas measurements are more reliable than are Astrup determinations in following the course of a patient in respiratory failure. The technique of arterial puncture is simple but cannot be relegated to the average laboratory technician. In smaller hospitals where arterial blood gas determinations are not available,

TABLE
SUMMARY OF ARTERIAL BLOOD GAS AND ASTRUP DATA

	75§	44	7.47	95					

*Normal = 41.6 + 0.42 × hemoglobin concentration in gm/100 ml.

†The data in this line were obtained on Feb. 13, 1967.

‡The data in this line were obtained on Feb. 23, 1967, while the patient was breathing 100% oxygen. Normal values under these conditions are 610 to 670 mm Hg.

§The data in this line were obtained after the patient had hyperventilated room air for 1 minute.

monitoring can be achieved with the Astrup technique[5] in cases of respiratory acidosis when abnormal shunting is not evident. Assessment of pH, carbon dioxide tension,[10] and the metabolic component of acid-base disturbance can be made with the Astrup technique, but information regarding oxygenation of the arterial blood must be estimated on a clinical basis.

Each patient with respiratory insufficiency should be observed at frequent intervals. If this is not possible, the patient should be transferred to a hospital with a respiratory care unit where 24-hour monitoring of blood gases and ventilation is possible. It is essential to know the severity of respiratory acidosis and whether it is complicated by metabolic (diabetic, renal, or lactic) acidosis or a metabolic (due to hypokalemia) alkalosis. Monitoring is essential during mechanical ventilation in chronic respiratory acidosis to prevent too rapid correction of the hypercapnia with the development of subsequent alkalosis and its consequent cardiac arrhythmias and central nervous system disorders.[11]

Case 7 is an example of primary alveolar hypoventilation in the obese[12,13] and demonstrates the usefulness of arterial gas studies not only in pinpointing the gas derangements but in establishing a diagnosis.

Summary

The interrelationship of ventilatory function, carbon dioxide tension, oxygen tension, and hydrogen ion concentration must be appraised in each clinical situation in which there is alveolar hypoventilation and respiratory acidosis. Treatment depends upon complete knowledge of acid-base abnormalities and careful monitoring of ventilation and blood gases. Cases are presented to show that, when hypoxia is related to alveolar hypoventilation or shunting of blood, data obtained from Astrup determinations do not provide adequate information without knowledge of arterial oxygen tensions.

the antacid puzzle

In peptic ulcer:

solved by Mylanta®

aluminum and magnesium hydroxides *plus* simethicone

"will it ease the pain?"

Mylanta helps relieve ulcer pain with the two most widely prescribed antacids: aluminum and magnesium hydroxides.

will it help "my gassy stomach"?

Mylanta *also* contains simethicone: for concomitant relief of G.I. gas distress.

"will this one taste O. K.?"

The *prolonged* acceptance of Mylanta was recently confirmed in 87.5% of 104 patients—after a total of 20,459 documented days of therapy.* *Danhof, I. E.: Report on file.

Composition: Each Mylanta chewable tablet or teaspoonful (5 ml.) contains: magnesium hydroxide, 200 mg.; aluminum hydroxide, dried gel, 200 mg.; simethicone, 20 mg. *Dosage:* One or two tablets (well chewed or allowed to dissolve in the mouth) or one or two teaspoonfuls to be taken between meals and at bedtime.

ATLAS CHEMICAL INDUSTRIES, INC.

No two women are quite alike...

and no other oral contraceptive is quite like Ovulen-21®

Each tablet contains ethynodiol diacetate 1 mg., mestranol 0.1 mg.

The progestin is distinctive, and for some women this may mean a different clinical response. The Compack® tablet dispenser is distinctive; its functional simplicity makes it virtually patient-proof. The acceptance of Ovulen-21 is distinctive... together with Ovulen®, it is more often prescribed than any other individual contraceptive product currently available.

Indication—Oral contraception.

Contraindications—Thrombophlebitis, thromboembolic disorders, cerebral apoplexy or a past history of these conditions, markedly impaired liver function, known or suspected carcinoma of the breast, known or suspected estrogen-dependent neoplasia, undiagnosed abnormal genital bleeding.

Warnings—Watch for the earliest manifestations of thrombotic disorders (thrombophlebitis, cerebrovascular disorders, pulmonary embolism, retinal thrombosis); if present or suspected discontinue the drug immediately.

British studies reported in April 1968[1,2] estimate there is a seven- to tenfold increase in mortality and morbidity due to thromboembolic diseases in women taking oral contraceptives. In these controlled retrospective studies, involving 36 reported deaths and 58 hospitalizations due to "idiopathic" thromboembolism, statistical evaluation indicated that the differences observed between users and non-users were highly significant. The conclusions reached in the studies are summarized in the table below:

Comparison of Mortality and Hospitalization Rates Due to Thromboembolic Disease in Users and Non-Users of Oral Contraceptives in Britain.

Category	Mortality Rates		Hospitalization Rates (Morbidity)
	Age 20-34	Age 35-44	Age 20-44
Users of Oral Contraceptives	1.5/100,000	3.9/100,000	47/100,000
Non-Users	0.2/100,000	0.5/100,000	5/100,000

No comparable studies are yet available in the United States. The British data, especially as they indicate the magnitude of the increased risk to the individual patient, cannot be applied directly to women in other countries in which the incidences of spontaneously occurring thromboembolic disease may differ.

Discontinue medication pending examination if there is sudden partial or complete loss of vision, or sudden onset of proptosis, diplopia or migraine. Withdraw medication if papilledema or retinal vascular lesions are found.

Since the safety of Ovulen in pregnancy has not been demonstrated, it is recommended that pregnancy be ruled out for any patient who has missed two consecutive periods before continuing the contraceptive regimen. If the patient has not adhered to the prescribed schedule the possibility of pregnancy should be considered at the first missed period.

A small fraction of the hormone agents in oral contraceptives has been identified in the milk of mothers receiving these drugs. The long-range effect to the nursing infant cannot be determined at this time.

Precautions—Pretreatment physical examination should include special reference to the breasts and pelvic organs, and a Papanicolaou smear.

Endocrine and possibly liver function tests may be affected by Ovulen. Therefore, it is recommended that such tests if abnormal be repeated after the drug has been withdrawn for two months.

Pre-existing uterine fibromyomas may increase in size under the influence of progestogen-estrogen preparations.

Because these agents may cause some degree of fluid retention, conditions which might be influenced by this factor, such as epilepsy, migraine, asthma, cardiac or renal dysfunction, require careful observation.

In breakthrough bleeding, and all irregular vaginal bleeding, consider nonfunctional causes. Adequate diagnostic measures are indicated in undiagnosed vaginal bleeding.

Carefully observe patients with a history of psychic depression and discontinue the drug if severe depression recurs.

Any possible influence of prolonged Ovulen therapy on pituitary, ovarian, adrenal, hepatic or uterine function awaits further study.

A decrease in glucose tolerance has occurred in a significant percentage of patients on oral contraceptives. The mechanism of this decrease is obscure. For this reason, diabetic patients should be observed carefully while receiving Ovulen.

Because of the effects of estrogens on epiphyseal closure Ovulen should be used judiciously in young patients in whom bone growth is not complete.

The age of the patient constitutes no absolute limiting factor, although Ovulen therapy may mask the onset of the climacteric.

The pathologist should be informed of Ovulen therapy when relevant specimens are submitted.

Adverse Reactions—A statistically significant association has been shown between use of oral contraceptives and the following serious adverse reactions: thrombophlebitis, pulmonary embolism.

Although available evidence is suggestive of an association, such a relationship has been neither confirmed nor refuted for the following serious adverse reactions: cerebrovascular accidents, neuro-ocular lesions, e.g., retinal thrombosis and optic neuritis.

The following adverse reactions are known to occur in patients receiving oral contraceptives: nausea, vomiting, gastrointestinal symptoms (such as abdominal cramps and bloating), breakthrough bleeding, spotting, change in menstrual flow, amenorrhea during and after treatment, edema, chloasma or melasma, breast changes (tenderness, enlargement, secretion), change in weight, changes in cervical erosion and cervical secretions, suppression of lactation when given immediately post partum, cholestatic jaundice, migraine, allergic rash, rise in blood pressure in susceptible individuals, mental depression.

Although the following adverse reactions have been reported in users of oral contraceptives, an association has been neither confirmed nor refuted: anovulation post treatment, premenstrual-like syndrome, changes in libido, changes in appetite, cystitis-like syndrome, headache, nervousness, dizziness, fatigue, backache, hirsutism, loss of scalp hair, erythema multiforme and nodosum, hemorrhagic eruption, itching.

The following laboratory results may be altered by oral contraceptives: hepatic function: increased sulfobromophthalein and other tests; coagulation tests: increase in prothrombin, Factors VII, VIII, IX and X; thyroid function: increase in PBI and butanol extractable protein bound iodine, and decrease in T^3 uptake values; metyrapone test; pregnanediol determination.

Before prescribing see Detailed Product Information.

SEARLE Where "The Pill" Began
G. D. SEARLE & CO., P. O. Box 5110, Chicago, Illinois 60680

If you think the pink pill for U.R.I. symptoms is built for speed and endurance you're on the right track.

Here is a tablet that begins to relieve symptoms of upper respiratory infection quickly—a tablet that works for hours to make it easy for your patient to enjoy continuous relief.
Novahistine Singlet combines effective dosage of an antipyretic-analgesic with a vasoconstrictor-antihistamine formulation to relieve not only the congestion, but also the fever and the aches and pains that almost always accompany upper respiratory infections.

A total daily dosage of 3 or 4 tablets will normally provide the continuous relief your patient expects. Use with caution in patients with severe hypertension, diabetes mellitus, hyperthyroidism or urinary retention. Caution ambulatory patients that drowsiness may result.

PITMAN-MOORE Division of The Dow Chemical Company, Indianapolis, Indiana.

Novahistine®
Singlet decongestant-analgesic

(Each tablet contains: phenylephrine hydrochloride, 40 mg.; chlorpheniramine maleate, 8 mg.; acetaminophen, 500 mg.)

DOW

Smiles speak louder than words

for the good taste of Soyalac

Milk-free, hypo-allergenic Soyalac has a pleasing taste that is eagerly accepted by most infants. It's similar to mother's milk in composition and assimilation, much like cow's milk in consistency and completely free of fibre. Extensive clinical data support Soyalac's value in promoting growth and development. Soyalac is also excellent for growing children and adults.

Cervical Lymphography

THE DEVELOPMENT of a technique for visualizing cervical lymphatics via the use of radiopaque contrast agents is of great interest and reflects the increasing importance of this new radiographic device.* Unfortunately no one technique has so far been effective in visualizing the entire lymphatic system. Considerable experience has been accumulated in lymphangiography of the lower part of the body; but, while this technique is quite effective in visualizing the lymphatics up to the level of approximately L-2, it is ineffective in covering the area above this, including the upper periaortic areas and the mediastinum. There are other radiographic techniques which may be useful in outlining pathological adenopathy in the blind areas, such as inferior vena cavogram and intravenous pyelogram, but neither of these techniques has been as effective as lymphangiography. Consequently, any technique which increases the area susceptible to lymphangiographic study is of potential importance.

There are two general areas in which lymphangiography can be useful. The first is in the accurate staging of a known lymphoma, which appears to be of particular importance in the case of individuals with Hodgkin's disease. The evidence that high dosage radiotherapy is quite effective in treatment, particularly of patients with localized involvement, is now quite convincing. However, in the selection of patients for this mode of therapy, it is important to pinpoint all involved areas. In this determination, lymphangiography has been of particular importance since it exposes a considerable area of possible adenopathy hitherto concealed. If used in conjunction with inferior vena cavograms and intravenous pyelography, lymphangiography is particularly effective in delineating possible involvement of the abdomen. Lymphangiography also has the advantage that it can be used to follow patients, since contrast medium remains in the nodes for a considerable period of time, and these nodes can be re-examined by plain films of the abdomen. Thus, by the use of these techniques, patients with widespread disease who are not suitable candidates for intensive radiotherapy can be eliminated from such programs, and other patients who have unsuspected areas of involvement can receive radiotherapy directed to all the diseased areas.

There are certain disadvantages to lymphangiography, however, which should be noted. First of all, it is a time-consuming process which requires the patience and interest of the radiologist. In addition, there is a slight risk attached to the procedure. This risk appears most marked in individuals who have extensive pulmonary disease, and in such individuals lymphangiography probably should not be done. Despite this problem, however, a large series of patients have been studied at several centers for study of lymphoma, in-

Morton Salt introduces will power in a shaker

You probably know how hard it is for your patients to stay on a low-sodium diet. They try, but simply can't cut out salt completely. Now there's a product that's far more dependable than will power: New Morton Half/Salt Mixture™. It contains half the sodium of table salt but gives your patients all the satisfaction of true salt flavor. If your patients think low-sodium diets are hard to swallow, let them use new Morton Half/Salt Mixture. It's a happy compromise.

cluding Stanford and Memorial Hospital in New York, and the technique has proved its utility in this broad experience.

Lymphangiography may also be of use in investigating a patient for an occult lymphoma. It is known that auto-immune hemolytic anemia may be the first manifestation of an underlying lymphosarcoma or Hodgkin's disease. Certain patients have been found who had no peripheral manifestations of lymphoma whatsoever and who had normal intravenous pyelograms. However, an abnormal lymphangiogram has been the first clue to the presence of an underlying lymphoma. Unfortunately, the technique has been of less value in the study of nonlymphomatous neoplasms.

For lymphangiography to be completely successful, however, it will first be necessary to make the procedure completely safe, relatively less time-consuming, and more effective in visualizing all the lymph node areas. If this can be accomplished, clinicians will have a tremendously powerful tool for the study of lymphoma.

Mediastinoscopic Diagnosis of Sarcoidosis*

WITH CURRENT METHODS of management, precise diagnosis of intrathoracic conditions is of increasing importance. Intelligent utilization of knowledge of the lymphatic drainage of the lungs and mediastinum has afforded a simple and safe means for diagnosis of certain conditions which affect this lymphatic system.

Since Daniels[1] originally described biopsy of the scalene lymph nodes, various extensions have been proposed to increase diagnostic efficiency. Maloney and associates'[2] biopsy of the right thoracic duct lymph node has significantly increased the yield of positive cervical explorations; the disease can be diagnosed by this means in 80% of patients with nonpalpable nodes.

Only when cervical exploration fails to provide diagnostic material is further extension of nodal biopsy indicated. Such procedures as Harken and co-workers'[3] cervicomediastinal exploration and Carlens'[4] mediastinoscopy have made it possible to obtain diagnostic material which heretofore required more formidable surgical exploration. When biopsy material from either the neck or the mediastinum demonstrates noncaseating granuloma on pathologic examination, it is important to culture this material to be certain that specific organisms are not present. Only in this way is the diagnosis of sarcoidosis made more certain.

It has been stated that mediastinoscopy, or even thoracotomy, may be necessary to differentiate tuberculous hilar lymphadenopathy and certain other conditions from sarcoidosis.[5] In most instances, however, the correct diagnosis can be established without resort to these procedures. The true nature of the disease can usually be appreciated after careful review of the patient's clinical status and laboratory data, including the results of skin tests, x-ray examination of the chest, microbiologic studies, and biopsy of the scalene or thoracic duct lymph nodes.

Is it depression?
He says "It's my stomach..."

...but his other symptoms:
functional somatic complaints, anxiety insomnia, anorexia, feelings of guilt strongly suggest an underlying depression.

when the diagnosis is depression

ELAVIL® HCl
(AMITRIPTYLINE HCl) MSD

Indications: Mental depression and mild anxiety accompanying depression.

Contraindications: Glaucoma and predisposition to urinary retention. Not recommended in pregnancy.

Precautions and Side Effects: Drowsiness may occur within the first few days of therapy. Patients should be warned against driving a car or operating machinery or appliances requiring alert attention. When depression is accompanied by anxiety or agitation too severe to be controlled by ELAVIL HCl alone a phenothiazine tranquilizer may be given concomitantly. Suicide is always a possibility in mental depression and may remain until significant remission occurs. Supervise patients closely in case they may require hospitalization or concomitant electroshock therapy. Untoward reactions have been reported after the combined use of antidepressant agents having varying modes of activity. Accordingly, consider possibility of potentiation in combined use of antidepressants. Monoamine oxidase inhibitor drugs may potentiate other drugs and such potentiation may even cause death; permit at least two weeks to elapse between administration of two agents; in such patients, initiate therapy with ELAVIL HCl cautiously with gradual increase in dosage required to obtain a satisfactory response. Caution patients about errors of judgment due to change in mood, and that the response to alcohol may be potentiated. May provoke mania or hypomania in manic-depressive patients.

Side effects include drowsiness; dizziness; nausea; excitement; hypotension; fine tremor; jitteriness; weakness; headache; heartburn; anorexia; increased perspiration; incoordination; allergic-type reactions manifested by skin rash, swelling of face and tongue, itching; numbness and tingling of limbs, including peripheral neuropathy; activation of schizophrenia which may require phenothiazine tranquilizer therapy; epileptiform seizures in chronic schizophrenics; temporary confusion, disturbed concentration or, rarely, transient visual hallucinations on high doses; evidence of anticholinergic activity, such as tachycardia, dryness of the mouth, blurring of vision, urinary retention, constipation; paralytic ileus; jaundice; agranulocytosis.

Careful observation of all patients is recommended. The antidepressant activity may be evident within 3 or 4 days or may take as long as 30 days to develop adequately, and lack of response sometimes occurs. Response to medication will vary according to severity as well as type of depression present. Elderly patients and adolescents can often be managed on lower dosage levels.

Supplied: Tablets ELAVIL HCl, containing 10 mg., 25 mg., and 50 mg. amitriptyline HCl, bottles of 100 and 1000; Injection ELAVIL HCl, in 10-cc. vials, containing per cc.: 10 mg. amitriptyline HCl, 44 mg. dextrose, 1.5 mg. methylparaben, and 0.2 mg. propylparaben.

For more detailed information, consult your Merck Sharp & Dohme representative or see the package circular.

MERCK SHARP & DOHME Division of Merck & Co. Inc. West Point Pa 19486

WHERE TODAY'S THEORY IS TOMORROW'S THERAPY

Infection in Hospitalized Patients

DRS. SALTER AND ZINNEMAN* in their comprehensive review of bacteremia and *Candida* septicemia draw attention to changes in medical practice that have altered the pattern of infection. There has been an increasing number of reports concerning infections associated with chemotherapy. Included among chemotherapeutic agents are antibiotics, steroids, and the various drugs used in the treatment of malignant disease. Infection is also noted with increasing frequency in association with other medical problems. An example is radiation therapy, which may be associated with an increased risk of infection. Also, the terminal event in leukemia, lymphoma, and metastatic malignancy is often related to infection. In addition, surgeons are implanting foreign substances in the form of prostheses with increasing frequency. Infections associated with foreign material are not easily controlled. Some patients are given drugs that alter their defense mechanism to aid in the acceptance of transplanted tissue. These individuals are more susceptible to infection, and when it occurs, treatment is usually very difficult.

There has also been a change in the type of organism encountered in that those with acquired or natural resistance to antibacterial drugs are more often associated with infection. Physicians are also finding more disease caused by organisms which were previously thought to be saprophytes. Some drugs such as steroids not only alter the immune mechanism of the body but also mask many of the signs and symptoms usually associated with infection.

The early recognition and proper antibacterial treatment of infections under these hazardous circumstances are imperative. The other side of the coin, of course, concerns prevention, and in this area there is much work to be done. Investigators are only now beginning to scratch the surface of more sophisticated means of protection for the individual and the hospital. Experiments are in progress in the use of plastic isolators, protective clothing, filters, laminar air flow, and various combinations of these protective barriers. Much of this work has been stimulated by the fact that it is now possible to maintain gnotobiotic or germ-free animals with only minimal difficulty. The outer-space program has also been helpful, since the need for dust-free, and in some instances germ-free, areas has led to rapid advances in construction of "clean rooms." Better sampling devices are also now available, which aid in the discovery of otherwise undetected microorganisms.

I am confident that in the foreseeable future far superior methods of isolation and protection of both patient and hospital will be available.

Let the Tonsil Go with the Adenoid

IN THE JUNE 1967 ISSUE Dr. Donaldson presents a provocative report on that often discussed subject "The Tonsil and Adenoid Problem."* As in all branches of medicine, the pendulum swings from unbridled enthusiasm to ultra conservatism and then perhaps stabilizes itself in the mid-road between the extremes.

Dr. Donaldson outlines the present indications for tonsil or adenoid surgery and points out that the history of the patient's illness is vital in making this decision. Here the role of the referring physician as careful observer is

most important. Donaldson's most controversial conclusion that adenoidectomy is often indicated without tonsillectomy will provoke disagreement. The temptation to remove the tonsils at the same time as the adenoids is great. While the child is under anesthesia one cannot always be certain that the tonsils are innocent. Further it may be unfair to expose the patient to a second surgical procedure. The fear of morbidity and postoperative complications from tonsillectomy should not be an important consideration in this day of excellent surgical management.

I believe that all doctors interested in the "tonsil and adenoid problem" should read and reread this excellent article, for it cannot but help in making for better management and understanding by those concerned.

Joseph L. Garten, M.D.
Minneapolis, Minnesota

Megaloblastic Anemia*

THE PAPER by Dr. Yutani and his associates* on gastrointestinal causes of megaloblastic anemia illustrates why so much of the outstanding work on the megaloblastic anemias has been carried out by workers in the field of gastroenterology. With few exceptions, an abnormality or an abnormal function in the gastrointestinal system is of primary etiologic importance in this type of anemia.

These authors discuss the findings of many workers who have studied auto-immune mechanisms involving parietal cell and intrinsic factor antibodies in addisonian pernicious anemia. Another study along this line, which has been of considerable interest, is that of Ardeman and Chanarin[1] who, along with a number of others interested in this disease, have studied the effect of adrenal corticosteroids on vitamin-B_{12} absorption in patients with pernicious anemia. In one investigation they observed 11 patients with vitamin-B_{12} deficiency. Eight of them had addisonian pernicious anemia, and five of these had intrinsic factor antibodies in their serum. Two had undergone partial gastrectomy for duodenal ulcer, and one had undergone total gastrectomy for carcinoma seven years previously.

These investigators observed that therapy with prednisone, usually 40 mg daily for three to five weeks, resulted in an improvement in vitamin-B_{12} absorption in seven of the eight patients with addisonian pernicious anemia. It was equally effective in patients with or without demonstrable intrinsic factor antibodies. They also noted that improvement in absorption of vitamin B_{12} preceded any decline in the titer of intrinsic factor antibodies. It was also recorded that, in this group of five patients with intrinsic factor antibodies in the serum, three had an increase in the amount of intrinsic factor produced; but in two there was little change.

Ardeman and Chanarin pointed out that the efficacy of steroids in improving vitamin-B_{12} absorption in almost all patients with pernicious anemia suggested that there may not be any real difference between those patients with and those without demonstrable serum antibodies. It was of interest, however, that they failed to elicit a response in the patients who had megaloblastic anemia after subtotal gastric resection. The lack of response suggested to the authors that the pathogenesis of the gastric atrophy in pernicious anemia might be different from the atrophy appearing in the gastric remnant after partial gastrectomy. This difference could be explained by the concept that in pernicious anemia the atrophy may be largely the consequence of an auto-immune mechanism, while after partial gastrectomy, it may be that ischemic factors are more important. The improvement in vitamin-B_{12} absorption before any change in titer of the intrinsic factor antibody in the blood suggested that these antibodies were of little significance, and it was proposed that the important antibodies were those in such tissues as the gastric mucosa and epithelial cells lining the villi in the ileum where they came in contact with the antigen.

Complexities in the pathogenesis of megaloblastic anemias continue to be demonstrated by a number of investigators, and pernicious anemia is no exception.

With an Investment Annuity, you can s-t-r-e-t-c-h the benefits of your tax-favored retirement plan by your personal control in the selection of growth-oriented investments.

First Investment Annuity Company of America has recently been admitted to Minnesota, and can now offer the unique Investment Annuity to the medical profession—to both *self-employed* and to *salaried* physicians—for use with tax-sheltered annuities and Keogh plans.

The new Investment Annuity provides the optimum in investment flexibility in tax-sheltered retirement plans.

This chart is an historical illustration of what the Investment Annuity retirement income benefits would have been if they had started at $100 per month in 1949, if the retiree's account had been invested in a typical growth-type mutual fund. The chart reflects the increasing market over the past 20 years; it is not to be construed as a forecast for the future.

With the Investment Annuity—

1. You or your chosen Investment Advisor may select the investments within a tax-sheltered annuity fund Account held by a custodian.

2. Investment changes within your personal account may be made freely, without incurring tax on income, or on short-term or long-term gains.

3. Benefits vary each year to reflect the investment performance of your personal Account.

4. Benefits may be guaranteed to last for life or on a joint and survivor basis, with payments guaranteed for 5, 10, or 15 years in any event.

5. Benefits for survivors can be increased with FIAC's optional low-cost one-year term insurance to provide growth-oriented, tax-favored lifetime income for your beneficiary.

Intravenous Regional Anesthesia*

RECENT MEDICAL literature frequently contains articles on the ease of performing regional intravenous anesthesia. This technique undoubtedly has wide application but, because of the apparent ease of achieving anesthesia, persons who are relatively inexperienced may well attempt to use it when adequate supportive facilities are not available. "Adequate supportive facilities" means necessary medication and equipment to combat complications that may result from the use of local anesthetic agents.

Before using the local anesthetic agents required for this technique, one should be thoroughly familiar with the proper handling of complications that may follow. If respiratory arrest should occur, the means and ability to assure the patient of an adequate airway should be available. Medication for stopping convulsions should always be at hand, and the person administering the anesthetic should know how to use such medication. If cardiovascular collapse should develop, one should be able to support the circulation adequately at a moment's notice. All in all, one should be prepared to cope with all eventualities.

I would like to stress that this technique is not to be used indiscriminately in a busy office practice just because it is easily performed. It is fraught with the usual dangers associated with anesthesia. Remember, there is no minor anesthetic procedure.

Charles J. Restall, M.D.
Rochester, Minnesota

Weakness and Chronic Heart Failure

IT HAS BECOME increasingly apparent in recent years that amyloidosis may present with a variety of clinical manifestations which could mimic a number of other clinical entities. In the case of amyloidosis of the heart presented by Lovshin,* it was necessary to pursue diagnostically several alternative possibilities, including mitral stenosis, left atrial tumor, thromboembolic pulmonary vascular disease, and constrictive pericarditis. This seems reasonable because cardiac problems of apparent obscure cause are often shown to be uncommon forms of common heart disease and as such may be amenable to cure or successful therapy. This is particularly important in a case of progressive and refractory congestive heart failure in which there is clinical or laboratory evidence suggestive of constrictive heart disease. In this instance, exploration of the pericardium is necessary to determine whether or not constrictive pericarditis is present.

The establishment of the diagnosis of cardiac amyloidosis is frustrating therapeutically, but, with a better understanding of the amyloid process, one can hope that successful medical therapy may become available in the future. Until then, it is conceivable that some patients refractory to all available forms of medical therapy may become amenable to the dramatic forms of surgical therapy currently under development.

John Merideth, M.D.
Rochester, Minnesota

You May Be Right

Lethargy Within the Profession

Our welfare departments are in a state of ecstasy. Why? Because of the lethargic attitude of hundreds of physicians who have taken a perfunctory stand on the responsibility of their doctor-patient relationship to their welfare patients—particularly those on Title XIX categorical aid.

From many reports—which are very possibly propaganda from our welfare department—many physicians are accepting assignment on Title XIX categorical aid. If those of us who are opposing governmental subjugation become swallowed up in governmental directives, red tape, additional billing, and increased clerical costs each of us can at least say, "I DID SPEAK UP."

In 1945 there was a situation analogous to the one we are now facing. May I quote from Pastor Martin Niemoller? "In Germany the Nazis came for the Communists and I didn't speak up because I was not a Communist. Then they came for the Jews and I did not speak up because I was not a Jew. Then they came for the Trade Unionists and I did not speak up because I was not a Trade Unionist. Then they came for the Catholics and I was a Protestant, so I did not speak up. Then they came for me. By that time there was no one to speak up for anyone." Unquote!

The Editor's Soliloquy

Manuscripts

Some people love to write and most people love to read. The editor loves both; but there can be a limit. A manuscript in the following vein, though informative and objective, can be appallingly tedious and inconsequential:

Title

"An Evaluation of Headache as It Pertains to Males and Females in Kandiyohi County During Hunting Season From October 1 to January 1.

With Special Emphasis on Posterior Occipital Headache

A Report on My Double-Blind Series of Five Consecutive and Unselected Cases.

Introduction

"This manuscript is written for the purpose of informing interested readers about headache as it occurs in Kandiyohi County . . . etc.

"The literature on the subject has been carefully examined and exhaustively reviewed, resulting in the finding that of 350 authorities listed in the References, 174 are cognizant and 176 unaware of the problems and complications involved. The author has personally and critically perused all of these references except the last 345, for the authenticity and perspicacity of which he accepts the word of Longtalk, Jabber and Longwinded, whose erudite resume was published in the Annals of 1946. (To antedate 1946 would seem unnecessary.)

"I now propose adding my own supplementary series.

Body of Manuscript

"In my professional experience with headaches, summed up in my series of five (four males and one female), 60% (3 cases) showed favorable and 40% (2 cases) unfavorable results, which seems to substantiate overwhelmingly the findings of Stretch and Strain and coworkers, who found favorable results in 51.58%. True, their series is somewhat larger; but the validity of any study lies not so much in its size as in the thoroughness and accuracy with which it is conducted. (Incidentally, I am omitting statistics on age and sex ratios as not significantly pertinent or contributory.) On the basis of my educated guess, therefore, I believe I am justified in making a reliable assumption in the affirmative—viz., a corroboration of the previous deductions already so conscientiously and laboriously arrived at by my distinguished predecessors in the field.

Comments

"With the numerous investigations of Knowitall et al. of Pepp State and the qualifying but nonetheless confirmatory analyses of Doubtful and Dubious of Modalities Institute on the Hudson, added to my own, it appears that headaches can be assured with the probability of error of only 1.5 to the nth squared power over 3.

Conclusion

"With this verified and therefore cogent figure I conclude my expatiation. I have cited the literature; I have added statistics based on my own five cases; and I have thereby concurred in a valuable if not momentous conclusion."

Editor's Note: An addendum of two more cases reached my desk subsequent to the presentation of this article for publication 4:32 p.m., October 1, 1955 (establishing priority) but I have chosen to exclude them from the series on the basis that no additional value would accrue from their inclusion.

Carl O. Rice, M.D.

Old Doc Hess says: From the spoken word to the readable manuscript there's been a lot of boiling and re-boiling.

There is a time to wink as well as to see.—Thomas Fuller

A once-popular treatment for back pains was to have the seventh son of a seventh son stand or walk on the patient's back.

The pain of earache was allegedly relieved by holding a hot roasted onion to the ear.

For headache, a sovereign remedy was to wear a snakeskin round one's head.

A realistic approach to pain relief

'Empirin'®

Compound with Codeine Phosphate gr. 1/2 No. 3

Each tablet contains:
Codeine Phosphate gr. 1/2 (Warning—May be habit forming), Phenacetin gr. 2 1/2, Aspirin gr. 3 1/2, Caffeine gr. 1/2.

keeps the promise of pain relief

'B.W. & Co.' narcotic products are Class "B", and as such are available on oral prescription, where State law permits.

BURROUGHS WELLCOME & CO. (U.S.A.) INC.
Tuckahoe, N.Y.

Louie lost weeks with acute shoulder bursitis. That's a lot of pain, stiffness and tenderness...and also a lot of fish. It might have been different with **Butazolidin® alka**

100 mg. phenylbutazone
100 mg. dried aluminum hydroxide gel
150 mg. magnesium trisilicate

If it doesn't work in a week, forget it

But please don't forget this:

Contraindications: Edema; danger of cardiac decompensation; history or symptoms of peptic ulcer; renal, hepatic or cardiac damage; history of drug allergy; history of blood dyscrasia. The drug should not be given when the patient is senile or when other potent drugs are given concurrently. Large doses of the alka formulation are contraindicated in glaucoma.

Warning: If coumarin-type anticoagulants are given simultaneously, watch for excessive increase in prothrombin time. Instances of severe bleeding have occurred. Persistent or severe dyspepsia may indicate peptic ulcer; perform upper gastrointestinal x-ray diagnostic tests if drug is continued. Pyrazole compounds may potentiate the pharmacologic action of sulfonylurea, sulfonamide-type agents and insulin. Carefully observe patients receiving such therapy. Use with caution in the first trimester of pregnancy and in patients with thyroid disease.

Precautions: Before prescribing, carefully select patients, avoiding those responsive to routine measures as well as contraindicated patients. Obtain a detailed history and a complete physical and laboratory examination, including a blood count. Patients should not exceed recommended dosage, should be closely supervised and should be warned to discontinue the drug and report immediately if fever, sore throat, or mouth lesions (symptoms of blood dyscrasia); sudden weight gain (water retention); skin reactions; black or tarry stools or other evidence of intestinal hemorrhage occur. Make complete blood counts at weekly intervals during early therapy and at 2-week intervals thereafter. Discontinue the drug immediately and institute countermeasures if the white count changes significantly, granulocytes decrease, or immature forms appear. Use greater care in the elderly and in hypertensives.

Adverse Reactions: The more common are nausea and edema. Swelling of the ankles or face may be minimized by withholding dietary salt, reduction in dosage or use of diuretics. In elderly patients and in those with hypertension the drug should be discontinued with the appearance of edema. The drug has been associated with peptic ulcer and may reactivate a latent peptic ulcer. The patient should be instructed to take doses immediately before or after meals or with milk to minimize gastric upset. Drug rash occasionally occurs. If it does, promptly discontinue the drug. Agranulocytosis, exfoliative dermatitis, Stevens-Johnson syndrome, Lyell's syndrome (toxic necrotizing epidermolysis), or a generalized allergic reaction similar to serum sickness may occur and require permanent withdrawal of medication. Agranulocytosis can occur suddenly in spite of regular, repeated normal white counts. Stomatitis, salivary gland enlargement, vomiting, vertigo and languor may occur. Leukemia and leukemoid reactions have been reported. While not definitely attributable to the drug, a causal relationship cannot be excluded. Thrombocytopenic purpura and aplastic anemia may occur. Confusional states, agitation, headache, blurred vision, optic neuritis and transient hearing loss have been reported, as have hyperglycemia, hepatitis, jaundice, hypersensitivity angiitis, pericarditis and several cases of anuria and hematuria. With long-term use, reversible thyroid hyperplasia may occur infrequently. Moderate lowering of the red cell count due to hemodilution may occur.

Dosage in Painful Shoulder: Initial: 3 to 6 capsules daily in 3 or 4 equal doses. Trial period: 1 week. Maintenance dosage should not exceed 4 capsules daily; response is often achieved with 1 or 2 capsules daily.

In selecting the appropriate dosage in any specific case, consideration should be given to the patient's weight, general health, age and any other factors influencing drug response.

For complete details, please see full prescribing information.

Geigy Pharmaceuticals
Division of Geigy Chemical Corporation
Ardsley, New York 10502

Butazolidin® alka Geigy

Capsules
100 mg. phenylbutazone
100 mg. dried aluminum hydroxide gel
150 mg. magnesium trisilicate

BU-6210

When it's more than a bad cold

your patient can feel better while he's getting better

Achrocidin®

Tetracycline HCl—Antihistamine—Analgesic Compound

Each tablet contains: ACHROMYCIN® Tetracycline HCl 125 mg.; Phenacetin 120 mg.; Caffeine 30 mg.; Salicylamide 150 mg.; Chlorothen citrate 25 mg.

In tetracycline-sensitive bacterial infection complicating respiratory allergy, ACHROCIDIN brings the treatment together in a single prescription—prompt relief of headache and congestion together with effective control of the organisms frequently responsible for complications leading to prolonged disability in the susceptible patient.

For children and elderly patients you may prefer caffeine-free ACHROCIDIN Syrup. Each 5 cc contains: ACHROMYCIN (Tetracycline) equivalent to Tetracycline HCl 125 mg.; Phenacetin 120 mg.; Salicylamide 150 mg.; Ascorbic Acid (C) 25 mg.; Pyrilamine Maleate 15 mg.

Contraindications: Hypersensitivity to any component.

Warning: In renal impairment, since liver toxicity is possible, lower doses are indicated; during prolonged therapy consider serum level determinations. Photodynamic reaction to sunlight may occur in hypersensitive persons. Photosensitive individuals should avoid exposure; discontinue treatment if skin discomfort occurs.

Precautions: Drowsiness, anorexia, slight gastric distress can occur. In excessive drowsiness, consider longer dosage intervals. Persons on full dosage should not operate vehicles. Nonsusceptible organisms may overgrow; treat superinfection appropriately. Treat beta-hemolytic streptococcal infections at least 10 days to help prevent rheumatic fever or acute glomerulonephritis. Tetracycline may form a stable calcium complex in bone-forming tissue and may cause dental staining during tooth development (last half of pregnancy, neonatal period, infancy, early childhood).

Adverse Reactions: *Gastrointestinal*—anorexia, nausea, vomiting, diarrhea, stomatitis, glossitis, enterocolitis, pruritus ani. *Skin*—maculopapular and erythematous rashes; exfoliative dermatitis; photosensitivity; onycholysis, nail discoloration. *Kidney*—dose-related rise in BUN. *Hypersensitivity* reactions—urticaria, angioneurotic edema, anaphylaxis. *Intracranial*—bulging fontanels in young infants. *Teeth*—yellow-brown staining; enamel hypoplasia. *Blood*—anemia, thrombocytopenic purpura, neutropenia, eosinophilia. *Liver*—cholestasis at high dosage.

Upon adverse reaction, stop medication and treat appropriately.

Curbstone Consultation

PLASMA PHENOLSULFONPHTHALEIN INDEX

QUESTION: What is the plasma phenolsulfonphthalein index test of renal function and what are its advantages over the standard PSP test?

ANSWER: The plasma phenolsulfonphthalein index test is based on serial determinations of plasma phenolsulfonphthalein plasma levels following the intravenous injection of a single dose of the dye. The index is determined by calculating the rate of decrease of the plasma phenolsulfonphthalein values over a given time period (usually 15-35 minutes) following the injection. Rate of fall of the plasma phenolsulfonphthalein plasma values are directly related to renal function.

The phenolsulfonphthalein index test overcomes several problems encountered in the standard plasma phenolsulfonphthalein test, such as those arising in cases of bilirubinuria, hematuria, urinary retention in the upper or lower urinary tract, and where difficulties are met in collection of urine specimens (poor patient cooperation, fistulas, etc.).

Harold D. Kletschka, M.D.
Houston, Texas

LUPUS ERYTHEMATOSUS

QUESTION: What is the clinical significance of the lupus erythematosus cell and how does the finding of such cells compare with the Hyland "Lupus Erythematosus Test" as a diagnostic feature?

ANSWER: Lupus erythematosus cell formation is thought to be due to an antibody to nucleoprotein. Lupus erythematosus cells are observed in systemic lupus erythematosus (about 75% of such cases), rheumatoid arthritis (about 10%), scleroderma (10%), and lupoid hepatitis. Although they have been recorded as occurring in association with certain drug reactions it is believed that most such cases on close investigation will be found to have an underlying lupus diathesis. It is futile to attempt correlation of positive lupus erythematosus cell test results with the clinical picture or as a guide to treatment. The Hyland "Lupus Erythematosus Test" results are positive in only about one third of patients with lupus erythematosus cells but is almost specific in detecting activity of systemic lupus erythematosus.

The Viewing Box

Routine Chest Film

ON HER FIRST hospital admission this 60-year-old white female was referred for evaluation of a routine chest film. A similar routine chest film done one year before had been read as normal.

This lady, on admission, revealed no respiratory symptoms except for a cold some two weeks previously. There was no chest pain, hemoptysis, dyspnea, or association with persons having tuberculosis, but since her cold, an intermittent non-productive cough had persisted. On direct questioning she admitted to progressive hoarseness over the previous 24 hours prior to admission. She had smoked one and one-half packs of cigarettes a day for the preceding 30 years, but had quit about two years before because of a mild non-productive morning cough.

Physical examination of the chest showed decreased breath sounds and fremitus in the left upper lobe, with some increased, coarse breath sounds in the left lower lobe. There were no rales or rhonchi. Indirect laryngoscopy revealed the left vocal cord to be paralyzed. Three days after admission the patient was noted to be markedly dyspneic with expiratory stridor.

The admission chest roentgenogram disclosed a large anterior mediastinal mass and atelectasis of the left upper lobe (Figures 1-a and 1-b).

What is your diagnosis? (See next page).

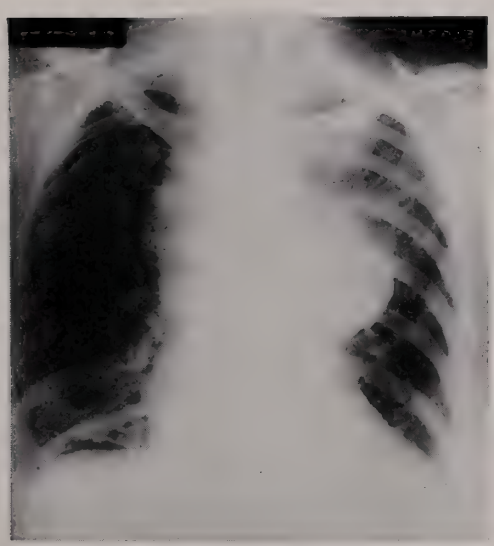

Figure 1-a.

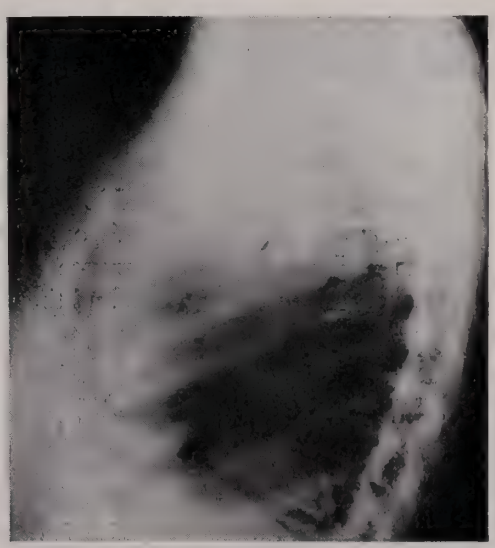

Figure 1-b.

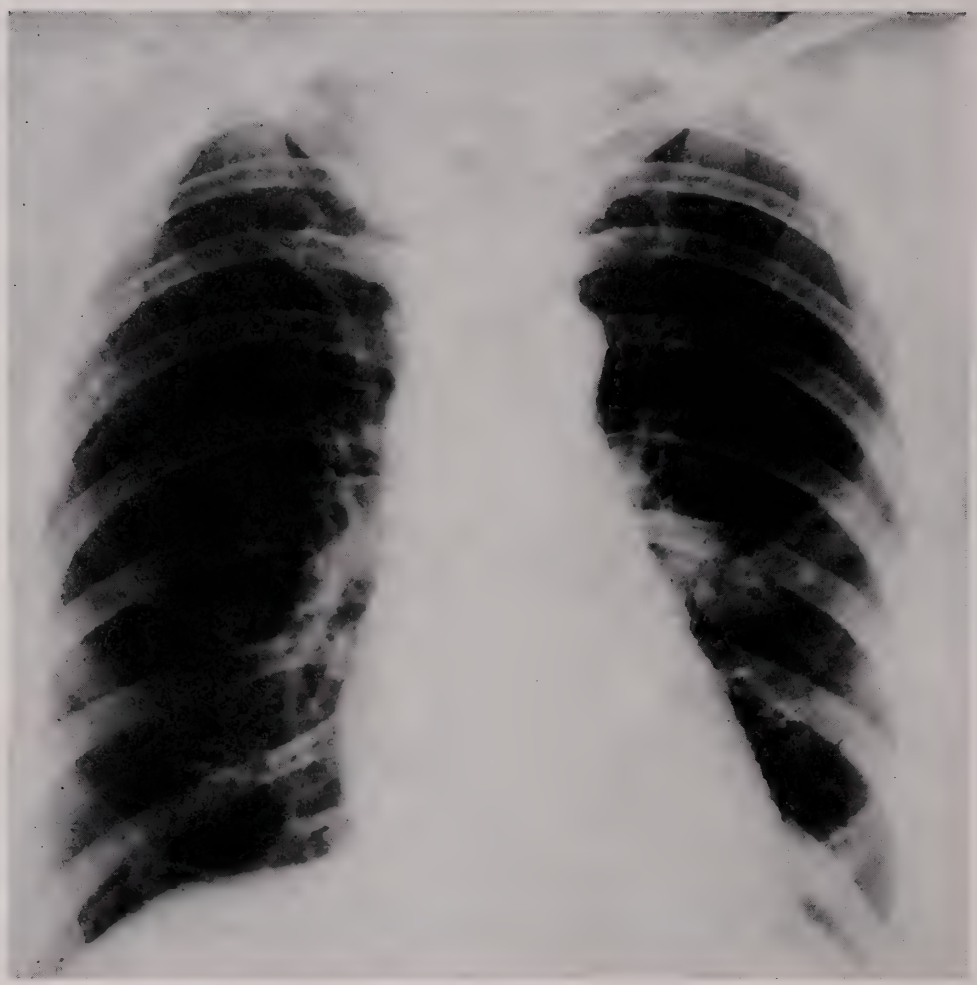

Figure 2.

Diagnosis: Poorly differentiated small cell carcinoma, with secondary atelectasis of the left upper lobe.

The differential diagnosis consistent with a rapidly expanding anterior mediastinal mass would be between that of lymphoma, carcinoma, or aneurysm. Sarcoid would be unlikely in so anterior a site as this (Figures 1-a and 1-b). The physician should consider carcinoma more likely when associated atelectasis of an entire lobe is present. This lady was given 10 treatments of cobalt 60 teletherapy with 2500 r to the mediastinum. Immediate symptomatic improvement was noted, and some two months later only residual fibrosis remains (Figure 2). Recurrence of the tumor and/or distinct metastases, however, are to be expected, and the prognosis remains grave.

Buttocks

We all have something to fall back on, and I never knew a phony who didn't land on it eventually.—Wilson Mizner

Fracture Conference

Problem Fractures in Children

The Elbow

Dr. Hamlet A. Peterson:*

We would like to present three challenging and interesting cases. Also, Dr. Goodwin has prepared a short review of the pertinent literature on one of the problems covered.

Report of Cases

Case 1

Dr. Richard C. Sweeting:†

The first case is that of a five-year-old girl who fell off her bicycle in June 1967. The physician in her home community found a simple oblique fracture of the middle third of the right ulna. Her arm was placed in a long arm cast, and the usual instructions and precautions were given. She was first seen at our clinic five weeks after the fracture, with her arm still in the cast.

Dr. Peterson:

According to the referring letter, there was a simple fracture of the ulna. Upon arrival the cast was removed, and roentgenograms were taken (Figure 1 A and B). Dr. Mess, how do you think the fracture is coming along?

Dr. C. F. Mess:‡

It looks as if there is no evidence of union now after five weeks. I would like to see some signs of bony union. There is still a fracture line between the segments.

Dr. Peterson:

At five weeks would you put her arm back in a cast?

---

*Instructor in Orthopedic Surgery, Mayo Graduate School of Medicine (University of Minnesota), Rochester, and Consultant, Section of Orthopedic Surgery, Mayo Clinic, Rochester.

†Resident in Orthopedic Surgery, Mayo Graduate School of Medicine, University of Minnesota, Rochester, Minnesota.

‡Resident in Orthopedic Surgery, Mayo Graduate School of Medicine (University of Minnesota), Rochester, Minnesota.

Conference held at the Mayo Clinic, Rochester, on April 1, 1968.

Dr. R. H. Turner:*

I probably would put her arm in a cast for another two or three weeks and see what it looked like at that time.

Dr. Peterson:

Her arm wasn't put in a cast. She was advised to begin motion.

Dr. Sweeting:

Five weeks later she returned; examination showed full extension but incomplete flexion. These roentgenograms were taken (Figure 1 C).

Dr. Peterson:

Now what do you think, Dr. Mess?

Dr. Mess:

There is a dislocation of the radial head.

Dr. Peterson:

In the history, emphasis was placed on the ulna, wasn't it? The patient's physician evidently missed detecting the dislocation of the radial head. It was also missed when she was first seen at our clinic (Figure 1 B). Ten weeks have elapsed since the fracture. Except for some loss of complete flexion the elbow has good motion, and the patient has no complaints. There is a rather obvious prominence over the lateral side of the elbow.

Dr. R. N. Stauffer:†

I think something needs to be done. It looks as if the ulna has shortened. How much pronation and supination did she have?

Dr. Peterson:

There was normal supination and pronation. After what duration would it become hazardous to reduce a dislocated radial head?

Dr. D. E. Fisher:‡

I think Dr. Pages' Instructional Course traced this problem. He believed that reduction ought to be attempted because the growth stimulation of the pressure on the end of the bone is lacking since there is no contact with the humerus. Also, the deformity will continue if reduction is not done.

Dr. Peterson:

If it was six months or one year later, would you do anything? There must be some sort of time limit. The girl is young.

Dr. Fisher:

I think that the girl will still have the basic problem no matter what the time limit is.

Dr. Peterson:

Even if the dislocation occurred one, two, or five years previously? Dr. Blount[1] has stated that after three months a dislocated radial head should not be reduced. There is usually full supination, diminished flexion, and an obvious deformity. Dr. Lipscomb, would you agree with leaving it unreduced after three months, but attempting reduction prior to this three-month limit?

---

†Resident in Orthopedic Surgery, Mayo Graduate School of Medicine, (University of Minnesota), Rochester, Minnesota.

‡Resident in Orthopedic Surgery, Mayo Graduate School of Medicine, (University of Minnesota), Rochester, Minnesota.

Dr. Paul R. Lipscomb:*

Dr. F. H. Stellings has reported a series of cases a few years ago and reported them again at the Academy Meeting after a long-term follow-up. The patients who had been left alone did far better and had better elbows as adults than those who had a late reduction of the radial head dislocation. This is at 10 weeks and right on the borderline. Certainly you are not going to find normal anatomic relationship, and some anatomic elements will be obliterated.

Dr. Peterson:

I researched the literature and found the three-months' figure to be gen-

*Professor of Orthopedic Surgery, Mayo Graduate School of Medicine, (University of Minnesota), Rochester, and Consultant, Section of Orthopedic Surgery, Mayo Clinic, Rochester.

Fig. 1—(Case 1). (*A*) and (*B*) Right forearm five weeks after injury. (*C*) Right forearm 10 weeks after injury. (*D*) Reduction of proximal portion of right radius was held with a Kirschner wire for three weeks. (*E*) Final result nine months after injury.

erally accepted. This research resulted in a two-week delay, but 12 weeks after injury the child underwent surgery. Dr. Sweeting, tell us what followed.

Dr. Sweeting:

With the child under general anesthesia, another attempt was made at closed reduction. This was unsuccessful. After an easy and uneventful open reduction, the annular ligament was reconstructed. The radial head was held in the reduced position by a Kirschner wire, as shown on the roentgenogram (Figure 1 D).

Dr. Peterson:

Three weeks later the wire was removed and the arm again put back into a long-arm cast. Six weeks after operation and four months after the fracture, the final cast was removed. A sling was worn for three weeks. The girl has done very well since then. Nine months after fracture (Figure 1 E) the range of motion was normal. So this case turned out well, and all concerned were happy. I am sure there is a time limit after which this type of injury should be left alone. Exactly what it is might depend somewhat on the age of the patient. This child was only five years old. I don't think the ulna was shortened, because the radial head was very easily reduced at surgery. Had the ulna been shortened, this would not have been so easy; then there would have been a question of how much force to apply. One would not want to traumatize the elbow or compress the epiphyseal plate in so doing.

Dr. Lipscomb:

Did you reconstruct the orbicular ligament?

Dr. Peterson:

Yes, a good portion was present, and it was sutured.

Dr. J. R. Sebald:*

How did you explain to the patient's parents the lack of treatment of the radial head dislocation initially?

Dr. Peterson:

They did not question it, and it wasn't brought up.

Dr. Sebald:

Did you tell them that the fracture had not united properly?

Dr. Peterson:

No. I think it was stated that the roentgenograms at 10 weeks showed a dislocation, and this was as far as the discussion went. Some patients' parents are more inquisitive than others.

Dr. Mess:

What would be the functional result of premature closure of the proximal radial epiphysis in a child of this age?

Dr. Peterson:

It would be similar to the situation resulting from removal of the radial head and would be rather drastic. Continued ulna growth would produce radial deviation of the hand and would limit forearm rotation.

Case 2

Dr. Sweeting:

The next case is that of an eight-year-old boy who fell off a slide. He

*Resident in Orthopedic Surgery, Mayo Graduate School of Medicine, (University of Minnesota), Rochester, Minnesota.

landed on his outstretched left arm and immediately had pain in his left elbow. There was slight swelling in the antecubital fossa on the left side and tenderness over both condyles, with a good radial pulse. Roentgenograms were taken (Figure 2A and B).

Dr. J. H. Shertzer:*

On the lateral view, the ulna is overriding the distal portion of the humerus.

Dr. Peterson:

You say on the lateral view? Do you think that's normal?

*Resident in Orthopedic Surgery, Mayo Graduate School of Medicine, (University of Minnesota), Rochester, Minnesota.

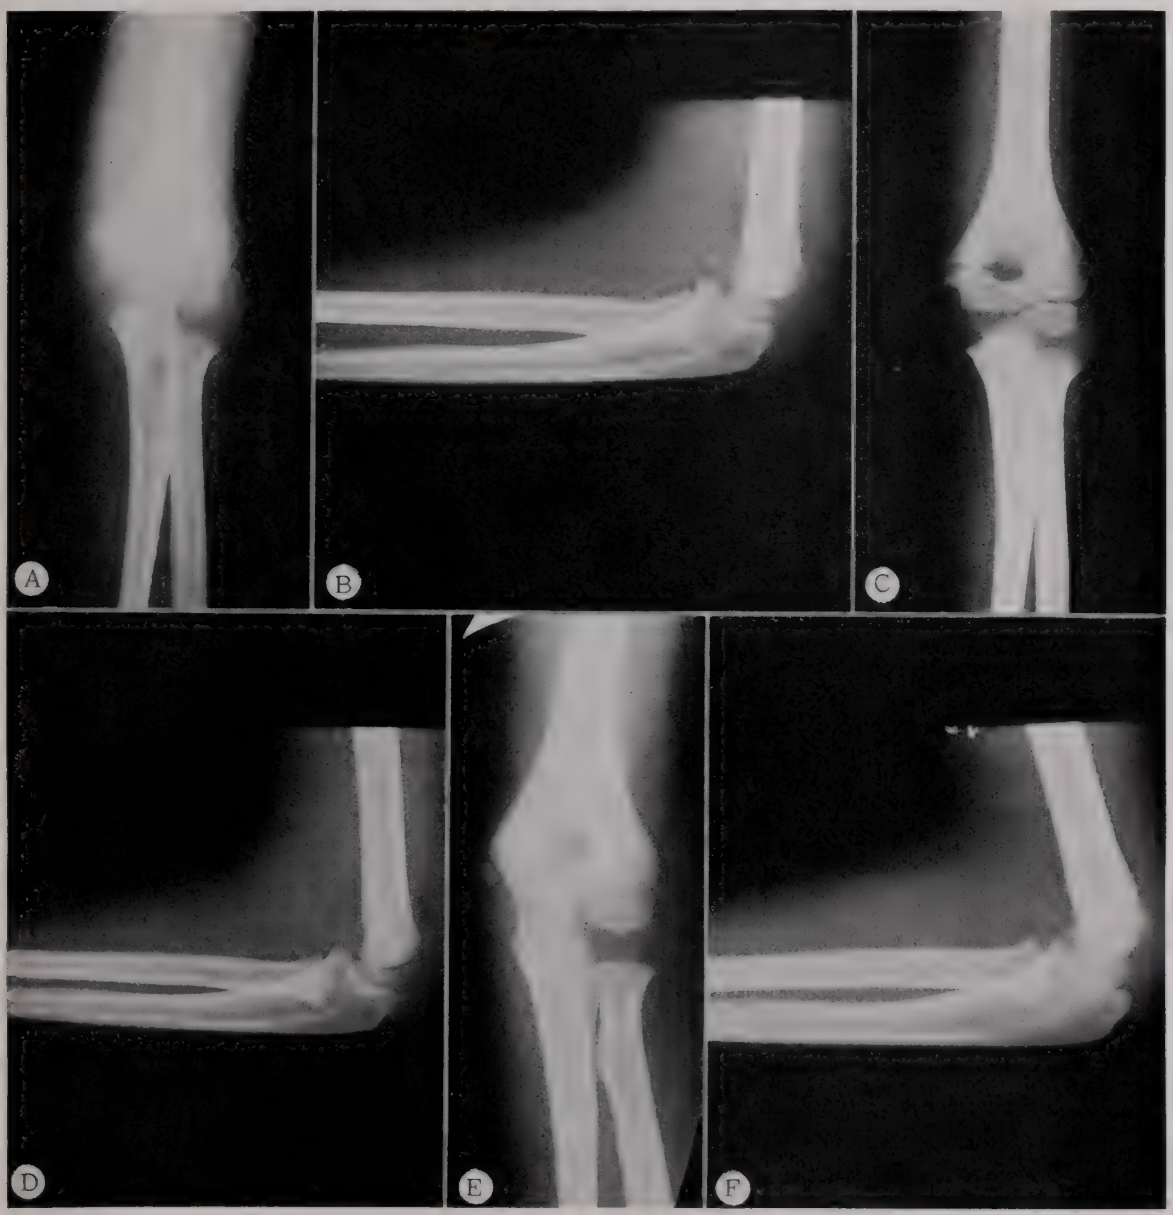

Fig. 2—(Case 2). (*A*) and (*B*) Lateral view of left elbow shows positive fat-pad sign. (*C*) and (*D*) In addition to the positive fat-pad sign, the anteroposterior view also shows a transcondylar fracture. (*E*) and (*F*) Ten weeks after injury, fat-pad sign is no longer present and the fracture is healing.

Dr. Shertzer:

It could be, now that I look at the anteroposterior views.

Dr. Peterson:

Films were interpreted by the radiologist as showing no abnormality.

Dr. S. Goldman:*

It looks as if there is a positive fat-pad sign.

Dr. Peterson:

What is a "fat-pad sign"?

Dr. Goldman:

Increased pressure within the elbow joint in a child causes some dislocation of the normal fat about the elbow. When this occurs, there is a radiolucent change in most of the tissues about the distal end of the humerus.

Dr. Peterson:

What do you think of the radiolucent area on a posterior aspect of the humerus? What does it indicate?

Dr. Goldman:

It usually indicates some intra-articular fracture.

Dr. Peterson:

Must it always be a fracture?

Dr. Goldman:

No, but there is always trauma around the elbow, with increased joint pressure.

Dr. Peterson:

Increased fluid in the elbow could be produced by a fracture. But a fracture was not seen on the roentgenogram. What would you do with this child?

Dr. Goldman:

I would put his arm in a large padded dressing and take more roentgenograms in a few days.

Dr. Peterson:

Do you think these roentgenograms are adequate? Additional roentgenograms seem necessary. Comparison roentgenograms of the opposite elbow looked identical, except for the absence of a fat-pad sign. Therefore, roentgenograms were taken again the same day. The new ones (Figure 2C and D) showed a fracture through the distal portion of the humerus: a transcondylar type of fracture. The child was immobilized. How long should the fat-pad sign remain positive?

Dr. Sweeting:

The cast was removed in three weeks and a sling applied.

Dr. Peterson:

Roentgenograms at six weeks (Figure 2 E and F) showed the fracture to be healing and the fat-pad sign to be absent. The patient did well.

Case 3

Dr. Sweeting:

Next is the case of a 14-year-old boy who slipped and fell on the sidewalk directly onto his flexed left elbow, striking the olecranon. Immedi-

*Resident in Orthopedic Surgery, Mayo Graduate School of Medicine, (University of Minnesota), Rochester, Minnesota.

Fig. 3—(Case 3). (*A*) and (*B*) Left-elbow intercondylar fracture and positive fat-pad sign. (*C*) and (*D*) Four months after injury, the fat pad has a normal appearance and the fracture has healed.

Note: For the reader's benefit, Figure 3 C and D is shown of the patient four months after injury. The fracture has healed; the fat-pad sign is no longer present.

ately he had pain and swelling at the site of injury. Roentgenograms were taken (Figure 3A and B).

Dr. Peterson:

Here again, on the lateral view, there is a positive fat-pad sign. Note the elevated "moon-shaped" area of radiolucency anteriorly. Normally, there should be a triangular area of radiolucency along the anterior portion of the humerus into the coronary fossa. There is also a fat-pad sign on the posterior aspect, which represents bulging or posterior displacement of the triceps tendon. Let's stop here and have Dr. Goodwin tell us about the fat-pad sign.

Fat-Pad Sign

Dr. H. N. Goodwin:*

The capsule of the elbow joint encloses the articular structures of the joint and is composed of a synovial and a fibrous layer. Between the fibrous and the synovial membranes there are three main collections of fat, the largest pad in the posterior region of the olecranon fossa. This pad is pressed into the fossa by the triceps mechanism during flexion. The other two pads are situated anteriorly in the coronoid and radial fossae into which they are pressed by the brachialis during extension. Bledsoe and Izenstark[2] demonstrated fat-pad displacement by injecting fluid into the elbow joint of cadavers. A true lateral projection of the elbow flexed to 90° is the optimal view for demonstrating fat-pad displacement. Because of the difference in x-ray absorption of fat, muscle, and bone, the fat is more readily visible on the roentgenogram.

In normal elbows, the anterior fat pads are visualized as a single triangular radiolucent area. Griffing[3] believes that the anterior fat-pad sign is of little value in the diagnosis of a traumatic lesion and is of academic interest only. The posterior fat pad is usually not visible on lateral flexion views of the normal elbow because the pad lies deep in the olecranon fossa and is overshadowed by bone. When displaced, this pad is seen as a radiolucent area above the olecranon fossa, posterior to the humerus. Often the interior border is concave, due to extrinsic pressure of the joint fluid. The demonstration of fat-pad displacement is suggestive of injury or disease about the elbow joint, including joint effusion secondary to arthritis and trauma.

Nelson[4] suggested that the posterior fat-pad sign is seen only in cases of trauma; he has stated that he has never seen fat-pad displacement caused by serous or purulent joint effusion. Norell,[5] however, reported seeing this sign in various types of arthritis of the elbow joint. If the joint capsule is ruptured, the escape of fluid prevents displacement of the fat pad. Also, if a fracture does not communicate with the synovial cavity, the pad may not be displaced. The posterior fat-pad sign has its greatest diagnostic use in obscure fractures about the elbow joint, especially those of the radial head. In closing, it can be said that evidence of fat-pad displacement, seen on the lateral roentgenographic view of the elbow, usually indicates pathologic change in the elbow.

Dr. Peterson:

In the literature there were only four references to this sign.[2-5] The important thing to remember is that two prerequisites are necessary: (1) an

*Resident in Orthopedic Surgery, Mayo Graduate School of Medicine, (University of Minnesota), Rochester, Minnesota.

intact capsule and (2) increased fluid within the joint that pushes the fat proximally. If the fat-pad displacement is seen, a search for a fracture should be made; however, other possible causes should be kept in mind.

Dr. L. F. A. Peterson:*

How long does the fat-pad sign remain positive after injury?

Dr. H. A. Peterson:

One article reported two to three weeks and another two to four days. Naturally, the length of time would depend on how fast the increased fluid in the joint could be absorbed.

Dr. M. B. Coventry:†

Our residents must remember the order of relative radiologic densities, because these are the basis of the fat-pad sign.

Dr. H. A. Peterson:

Thank you, Dr. Coventry. The order of relative density is fat, muscle, fluid, and bone.

Our time is nearly up; we must adjourn. These cases illustrate three salient points. First: In the event of a fracture of the midshaft of the ulna, one should always look for an associated dislocation of the same radial head. When this occurs, it is referred to as a Monteggia fracture, and treatment must be directed not only at the reduction of the fracture but also at the replacement of the dislocated head. Second: If the dislocation of the radial head is recognized late, as in our first case, an attempt at open reduction is justified up to three months after the injury. Third: The presence of the positive fat-pad sign should indicate to the practitioner that pathologic change exists in the elbow joint or the distal portion of the humerus.

Dermatology

Rosacea

ROSACEA (ACNE ROSACEA) is a common skin disease which affects the face. It may cause considerable embarrassment to the affected individual, for the layman often associates rosacea with gluttony and the excessive consumption of alcohol. The disease may occur in either men or women and is rare before the third decade.

Symptoms

Rosacea appears exclusively on the face and is most pronounced on the so-called flush areas (cheeks, nose, center forehead). Various stages may be recognized but are by no means distinct or exclusive from each other. The erythematous stage is characterized by flushing of the cheeks, nose, forehead and chin. The erythema is usually transient at first, lasting only a few hours. It may be induced by cold, heat, alcohol, spicy foods, coffee, etc. Nervous tension may also be associated with the flushing. Within varying periods of time telangiectasia of the superficial blood vessels occurs, resulting in a permanent erythema in the affected areas.

As a rule, there is an associated seborrhea involving the face and/or scalp, while the orifices of the sebaceous glands become prominent. The process may progress no further; however, in some individuals superficial or deep papules

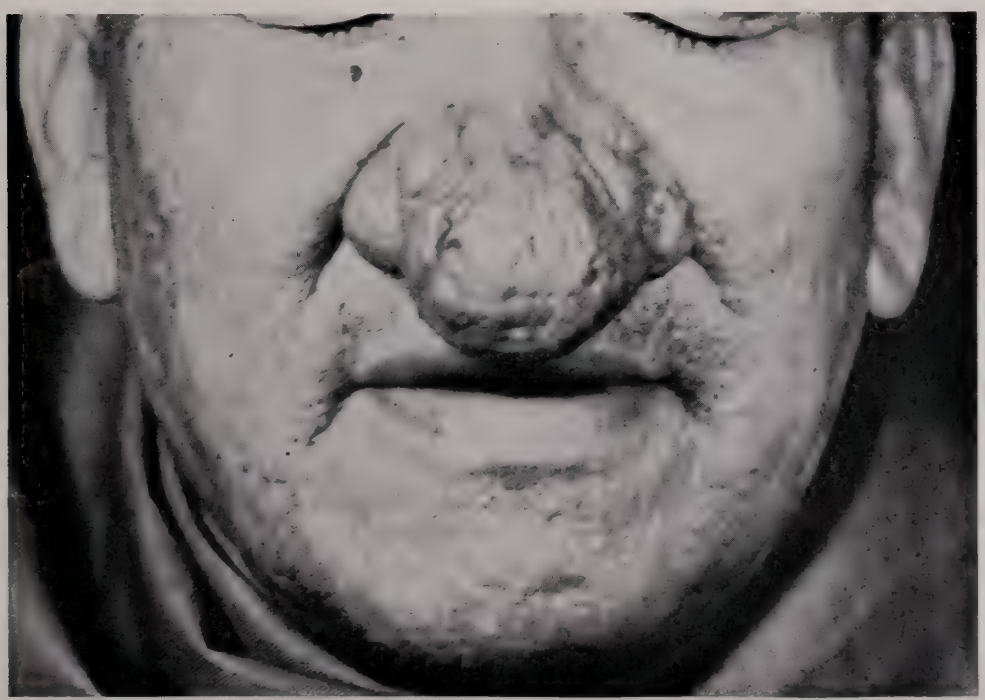

Figure.

and pustules occur. Such lesions resemble those of acne vulgaris, although the underlying erythema and the distribution, as well as age, help to differentiate the two conditions. In some cases the disease continues and deep cystic nodules and pustules develop. The lesions may even become abscesses with discharging sinuses. Scarring similar to that of acne vulgaris may occur.

A marked increase in size of the sebaceous glands can lead to progressive hypertrophy and lobulation of the nose called rhinophyma (Figure). The glandular orifices become conspicuous and an oily seborrhea is present. This latter stage is most common in men and rarely occurs in women. Fortunately most cases of rosacea remain relatively mild and present only as an erythema with an occasional papulopustular component. At times a blepharitis and conjunctivitis may be present with rosacea, and less commonly there may be a keratitis, iritis, and episcleritis. In the cornea a pannus composed of fine vessels may be found along with infiltrations. With these changes ulcerations and scarring can occur.

Diagnosis

Differential diagnosis includes acne vulgaris, lupus* erythematosis and photoallergic reactions. Acne vulgaris occurs in a younger age group, usually is not limited to the flush areas and lacks the underlying erythema and telangiectasia. Lupus erythematosus lacks the papulopustular component and frequently shows some degree of atrophy. Photoallergic reactions are revealed by a history of onset and exacerbation following sunlight exposure. Such reactions are not limited to the face but may involve ears, neck, arms or any exposed area. As a rule this eruption lacks the pustular component of rosacea. At times, rosacea may be made worse by exposure to sunlight, a situation which can create confusion with both photoallergies and lupus erythematosus.

Etiology

The cause of rosacea is undetermined. Certain factors are known to aggravate rosacea, such as nervous tension, hot or spicy foods, coffee, alcohol and exposure to extremes of temperature. In addition, gastric or hepatic disease, focal infection, and menstrual irregularities have been implicated. However, in many cases none of these factors is demonstrable.

Treatment

Treatment of rosacea is essentially a management problem, for eradication of this condition cannot as yet be achieved. First, adequate cleansing with soap and water and the use of various drying preparations are helpful. The patient should be instructed to follow a bland diet with avoidance of foods already mentioned. In the pustular forms small dosages of systemic antibiotics such as tetracycline are often beneficial. Plastic surgery may be indicated in rhinophyma to reduce the deformity. The patient should be informed that the disease tends towards chronicity and that control of the clinical manifestations is often all that can be achieved, although especially in women there may be gradual spontaneous improvement.

Willard C. Peterson, Jr., M.D.
Minneapolis, Minnesota

*See Test Your Word Score Page 1757.

As the Chinese doctor said to his patient, "Long time no fee."

In the complex picture of moderate to severe anxiety...

there is a new reason for prescribing Mellaril (Thioridazine HCl)

effectiveness in mixed anxiety-depression

Long recognized for its usefulness in the treatment of moderate to severe anxiety, Mellaril is now also known to be effective against mixed anxiety-depression.

Often the symptoms of anxiety states are difficult to sort out—even with the most careful probing. The patient may manifest symptoms of agitation, restlessness, insomnia, somatic complaints. But what of the depression that may be mixed in the total picture? It is reassuring to know that Mellaril may be prescribed—with strong possibilities of success—when there is anxiety alone or a mixture of anxiety and depression.

Before prescribing or administering, see Sandoz literature for full product information, including adverse reactions reported with phenothiazines. The following is a brief precautionary statement.

Contraindications: Severe central nervous system depression, comatose states from any cause, hypertensive or hypotensive heart disease of extreme degree.

Warnings: Administer cautiously to patients who have previously exhibited a hypersensitivity reaction (e.g., blood dyscrasias, jaundice) to phenothiazines. Phenothiazines are capable of potentiating central nervous system depressants (e.g., anesthetics, opiates, alcohol, etc.) as well as atropine and phosphorus insecticides. During pregnancy, administer only when necessary.

Precautions: There have been infrequent reports of leukopenia and/or agranulocytosis and convulsive seizures. In epileptic patients, anticonvulsant medication should also be maintained. Pigmentary retinopathy may be avoided by remaining within the recommended limits of dosage. Administer cautiously to patients participating in activities requiring complete mental alertness (e.g., driving). Orthostatic hypotension is more common in females than in males. Do not use epinephrine in treating drug-induced hypotension. Daily doses in excess of 300 mg. should be used only in severe neuropsychiatric conditions.

Adverse Reactions: *Central Nervous System*—Drowsiness, especially with large doses, early in treatment; infrequently, pseudoparkinsonism and other extrapyramidal symptoms; nocturnal confusion, hyperactivity, lethargy, psychotic reactions, restlessness, and headache. *Autonomic Nervous System*—Dryness of mouth, blurred vision, constipation, nausea, vomiting, diarrhea, nasal stuffiness, and pallor. *Endocrine System*—Galactorrhea, breast engorgement, amenorrhea, inhibition of ejaculation, and peripheral edema. *Skin*—Dermatitis and skin eruptions of the urticarial type, photosensitivity. *Cardiovascular System*—Changes in the terminal portion of the electrocardiogram have been observed in some patients receiving the phenothiazine tranquilizers, including Mellaril (thioridazine hydrochloride). While there is no evidence at present that these changes are in any way precursors of any significant disturbance of cardiac rhythm, several sudden and unexpected deaths apparently due to cardiac arrest have occurred in patients previously showing electrocardiographic changes. The use of periodic electrocardiograms has been proposed but would appear to be of questionable value as a predictive device. *Other*—A single case described as parotid swelling.

Mellaril®
(Thioridazine HCl) 25 mg. t.i.d.

for moderate to severe anxiety and mixed anxiety-depression

SANDOZ SANDOZ PHARMACEUTICALS, HANOVER, N. J. 68-169

Q. How much does the **anticostive*** **hematinic** cost?

A. No more than costive hematinics cost!

The anticostive hematinic is

PERITINIC®

Hematinic with Vitamins and Fecal Softener

A tablet-a-day provides:

● Elemental Iron (as Ferrous Fumarate)	100 mg
● Dioctyl Sodium Sulfosuccinate (to counteract constipating effect of iron)	100 mg
Vitamin B_1	7.5 mg
Vitamin B_2	7.5 mg
Vitamin B_6	7.5 mg
Vitamin B_{12}	50 mcgm
Vitamin C	200 mg
Niacinamide	30 mg
Folic Acid	0.05 mg
Pantothenic Acid	15 mg

Bottles of 60

*

anticostive, *adj.* (*anti* opposed to + *costive* causing constipation.) Against constipation. Now isn't that a good idea in an iron-containing hematinic?

Lederle LEDERLE LABORATORIES
A Division of American Cyanamid Company
Pearl River, New York 10965

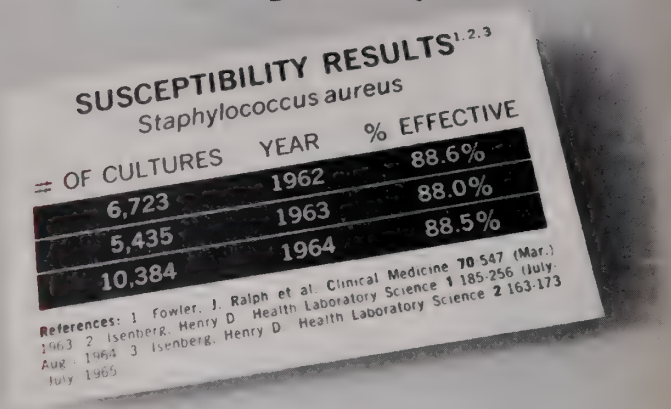
TAO® (triacetyloleandomycin)

Brief Summary

INDICATIONS: Include staphylococci, streptococci, pneumococci and gonococci. Recommended for acute, severe infections where adequate sensitivity testing has demonstrated susceptibility to this antibiotic and resistance to less toxic agents.

CONTRAINDICATIONS: Contraindicated in pre-existing liver disease or dysfunction, and in individuals hypersensitive to the drug.

PRECAUTIONS: CAUTION: USE OF THIS DRUG MAY PRODUCE ALTERATIONS IN LIVER FUNCTION TESTS AND JAUNDICE. CLINICAL EXPERIENCE AVAILABLE THUS FAR INDICATES THAT THESE LIVER CHANGES WERE REVERSIBLE FOLLOWING DISCONTINUATION OF THE DRUG.



Not recommended for prophylaxis or in the treatment of infectious processes, which may require more than ten days continuous therapy. In view of the possible hepatotoxicity of this drug when therapy beyond ten days proves necessary, other less toxic agents should be used. If clinical judgment dictates continuation of therapy for longer periods, serial monitoring of liver profile is recommended, and the drug should be discontinued at the first evidence of any form of liver abnormality. When treating gonorrhea in which lesions of primary or secondary syphilis are suspected, proper diagnostic procedures, including dark-field examinations, should be followed. In other cases in which concomitant syphilis is suspected, monthly serological tests should be made for at least four months. When used in streptococcal infections, therapy should be continued for ten days to prevent the development of rheumatic fever or glomerulonephritis. The use of antibiotics may occasionally permit overgrowth of nonsusceptible organisms. A resistant infection or superinfection requires re-evaluation of the patient's therapy. In the event such occurs with this drug the medication should be discontinued, and specific antibacterial and supportive therapy instituted.

ADVERSE REACTIONS: Although reactions of an allergic nature are infrequent and seldom severe, those of the anaphylactoid type have occurred on rare occasions.

OMNI-TUSS® b.i.d.

. . . **because** OMNI-TUSS is indicated for cough associated with upper respiratory tract infections, bronchitis, bronchiectasis, bronchial asthma, emphysema, sinusitis and rhinitis, hay fever, or other allergic conditions. Any of these conditions may exhibit the general symptom syndrome—coughing, wheezing, bronchospasm, and tenacious mucus—which may benefit from the antitussive, bronchodilative, antihistaminic, and expectorant action of Omni-Tuss.

The therapeutic usefulness of Omni-Tuss is enhanced by a unique resin complex formulation providing the clinically desirable advantages of: (1) uniform drug availability throughout an extended period, (2) 8 to 12 hours of symptomatic control, (3) minimal dosage requirement, (4) minimal side effects.

Economical, efficient **b.i.d.** dosage—extremely well-tolerated by children, 6-12, and adults.

'Omni Tuss' Suspension: Each teaspoonful (5 cc.) contains 10 mg. codeine (Warning: May be habit-forming), 5 mg. phenyltoloxamine, 3 mg. chlorpheniramine, 25 mg. ephedrine, all as cation exchange resin complexes of sulfonated polystyrene, and 20 mg. guaiacol carbonate.

Available on prescription only. Class X exempt narcotic. Permissible on oral prescription.

Dosage: *Adults:* 1 teaspoonful (5 cc.) q12h.
Children (6-12 *years*): ½ teaspoonful q12h.

Side Effects: Minimal, but when encountered may include jitteriness, nausea, drying of mouth, insomnia, constipation, which disappear upon adjustment of the dose or discontinuance of treatment.

Precautions and Contraindications: For complete detailed information, refer to package insert or official brochure.

Advances

The Choice of Antibiotics in Management of Bacteremia and Shock*

ALTHOUGH ALMOST any bacterial species can produce bacteremia under certain circumstances, some species are more frequently responsible.[1,2] It is the antibacterial drugs employable against these more frequently responsible bacterial species that are considered here.

Bacteremic shock refers to peripheral vascular collapse complicating bacterial invasion of the bloodstream. Although this type of shock is often emphasized as complicating bacteremia due to gram-negative bacilli,[1,3-13] it may also complicate other bacteremias, such as staphylococcemia and meningococcemia.

Some Principles of Management

Results of blood cultures and in-vitro† bacterial inhibition tests are mainly of retrospective value in the management of bacteremia, because antibacterial therapy often is begun empirically before such data are available. To postpone therapy until the results of such tests are reported would mean a delay of 24 to 48 hours and an increased chance of mortality.

The principles of antibacterial management of patients having bacteremia can be summarized as follows: (1) When cultures of blood are reported to grow bacteria, or when samples of blood for microbiologic study have been obtained from a patient suspected clinically of having bacteremia, antibacterial treatment is initiated empirically. (2) Reevaluation is made if in-vitro bacterial inhibition tests later indicate less than optimal choice of an antibacterial regimen, but the use of the regimen is continued unaltered if the patient is doing well. (3) The regimen is administered in adequate dosage for a sufficient time.

Pathogens and Regimens

A general summary of pathogens and regimens is shown in Table 1 and the dosage of the applicable drugs is given in Table 2. The drugs are listed in order of choice to parallel the severity of the infection, and, generally, those in decreasing order are somewhat less effective or are more likely to be toxic. Of course, in some cases, several agents are recognized as being effective. In certain instances, a drug is preferred because the physician himself has had greater experience with it. Other drugs not listed may show some activity against a given bacterial species. Also, the antibacterial regimen selected for use in a given instance may reflect such factors as the patient's general condition and resistance, his allergic diathesis, and his ability to accept the regimen by the route designated.

In general, combinations of drugs should be reserved for situations that demand treatment while microbiologic data are awaited, for polymicrobic infections, and for instances of bacteremia wherein there are indications that an enhanced effect is possible.

Staphylococcal Bacteremia

In patients having staphylococcal bacteremia, certain antistaphylococcal drugs that have been effective in the past are infrequently employed at present, largely because the unavailability of microbiologic data—especially the results of in-vitro bacterial inhibition tests—often results in the use of a given drug and its continued use thereafter when the patient responds well. If such data were more speedily reportable, perhaps one of these alternative drugs could be employed in a given situation and there would be less concern about emergence of bacterial strains resistant to the drugs more commonly used at present.

The best treatment of staphylococcal bacteremia remains pencillin G therapy, provided the organisms are susceptible to it. However, as is well known, the number of staphylococci resisting the action of penicillin G makes it imperative to use other drugs in the empiric management of serious staphylococcal infections. Consequently, in cases wherein the patient is not allergic to the penicillins and in whom there are clinical or cultural indications that a staphylococcus is the cause of bacteremia, the physician commonly administers a penicillinase-resistant penicillin, such as methicillin, oxacillin, or nafcillin, at least until adequate microbiologic data become available. When these drugs are not applicable, as in patients who have a known allergy to the penicillins, cephalothin may be tried. How-

TABLE I
ANTIBIOTICS OF CHOICE IN BACTEREMIA DUE TO INDICATED ORGANISMS

Organism	Antimicrobial agents		
	First choice	Second choice	Third choice
Staphylococcus aureus and staphylococcus coagulase-negative	Bactericidal effect: pencillin G or a penicillinase-resistant pencillin	Vancomycin or cephalothin	Kanamycin, ristocetin, bacitracin, or neomycin
	Bacteriostatic effect: erythromycin or lincomycin	Novobiocin	Chloramphenicol
Streptococcus pyogenes	Penicillin G	Erythromycin	Cephalothin or lincomycin
Streptococcus viridans (examples, *S. mitis, S salivarius*)	Penicillin G, alone or with streptomycin	Erythromycin	Cephalothin, lincomycin, novobiocin, or vancomycin
Enterococcus (example, *S. faecalis*); anaerobic streptococci; microaerophilic streptococci	Penicillin G or ampicillin with streptomycin or kanamycin	Vancomycin	Ristocetin or erythromycin-streptomycin
Diplococcus pneumoniae	Penicillin G	Erythromycin	Cephalothin or lincomycin
Neisseria meningitidis (intracellularis)	Penicillin G	Erythromycin	A tetracycline or chloramphenicol
Neisseria gonorrhoeae	Penicillin G	Erythromycin	A tetracycline
Shigella	Ampicillin	A polymyxin	Kanamycin or chloramphenicol
Escherichia	Ampicillin or cephalothin	A polymyxin	Kanamycin or chloramphenicol
Salmonella typhi	Chloramphenicol	Ampicillin	
Other *Salmonella* and *Arizona*	Ampicillin	Kanamycin	A polymyxin, a tetracycline, or chloramphenicol
Citrobacter	A polymyxin	Kanamycin	A tetracycline or chloramphenicol
Klebsiella	Cephalothin	A polymyxin	Kanamycin or chloramphenicol
Enterobacter	A polymyxin	Kanamycin	
Serratia	Kanamycin		
Proteus mirabilis	Penicillin G	Ampicillin	Cephalothin, novobiocin, kanamycin, or chloramphenicol
Proteus vulgaris, P. morganii, and *P. rettgeri;* and *Providence*	Kanamycin	Chloramphenicol	Cephalothin
Pseudomonas	A polymyxin		
Mimeae (Mima polymorpha and *Herellea vaginocola)*	A tetracycline and either kanamycin or a polymyxin		
Bacteroides	A tetracycline	Chloramphenicol	Penicillin G or cephalothin
Data Insufficient to Generalize Regarding Management of Certain Pathogens (Alcaligenes, Flavobacterium, Moraxella, and so forth)			
Clostridia	Penicillin G	Erythromycin	A tetracycline
Listeria monocytogenes	Penicillin G	A tetracycline	Erythromycin

ever, some workers would point out that vancomycin is an effective antistaphylococcal drug, and would choose it over cephalothin. Cephaloridine is not considered under these circumstances, because it is not recommended for use unless in-vitro bacterial inhibition tests indicate its applicability; also, dichotomies between in-vitro testing and in-vivo achievability may make cephaloridine a somewhat hazardous antistaphylococcal drug. Under present circumstances, erythromycin, lincomycin, and novobiocin have infrequent use but might have increased use if their in-vitro applicability were known earlier in the course of the infection. Kanamycin, ristocetin, and chloramphenicol also have infrequent use as anti-

TABLE 2
DOSAGE OF ANTIBIOTICS IN BACTEREMIA

Agent	Route of administration		
	Oral	Intramuscular	Intravenous
Penicillin G (benzyl penicillin), and penicillin V or phenethicillin	Penicillin V or phenethicillin, 200,000 units (125 mg)-800,000 units 4-6 times daily*	Aqueous crystalline penicillin G, 4,000,000-12,000,000 units daily	Penicillin G, 6,000,000 units or more
Methicillin		4-6 gm/day in 4-6 divided doses	4-24 gm/day in 4-12 divided doses
Oxacillin	2-6 gm/day in 4-6 divided doses*	4-6 gm/day in 4-6 divided doses	4-24 gm/day in 4-12 divided doses
Cloxacillin	1-6 gm/day in 4-6 divided doses*	Commercially unavailable in USA	Commercially unavailable in USA
Dicloxacillin	1-3 gm/day in 4-6 divided doses*	Commercially unavailable in USA	Commercially unavailable in USA
Nafcillin	2-6 gm/day in 4-6 divided doses*	4-6 gm/day in 4-6 divided doses	4-24 gm/day in 4-12 divided doses
Ampicillin	2-6 gm/day in 4-6 divided doses*†	4-6 gm/day in 4-6 divided doses	4-12 gm/day in 4-12 divided doses
Streptomycin	Poorly absorbed	2 gm/day in 2 divided doses not to exceed 2 wk or 1 gm daily in 2 doses not to exceed 4 wk	
Kanamycin	Poorly absorbed	1-1.5 gm/day in 2-3 divided doses	1 gm/day in 2 divided doses
Tetracyclines	2 gm/day in 4 divided doses*†	Not recommended	1-2 gm/day in 2-4 divided doses
Chloramphenicol	3 gm/day in 6 divided doses*	3-4 gm/day in 3-4 divided doses	2-4 gm/day in 2-4 divided doses
Erythromycin	2 gm/day in 4 divided doses*	Not recommended	2-4 gm/day in 2-4 divided doses
Novobiocin	2 gm/day in 4 divided doses*	2 gm/day in 2 divided doses	2 gm/day in 2-4 divided doses
Lincomycin	2 gm/day in 4 divided doses*	1,200-1,800 mg/day in 2 or 3 divided doses	1,200-1,800 mg/day in 2 or 3 divided doses
Polymyxin B	Poorly absorbed	150-200 mg/day in 3 or 4 divided doses	150-200 mg/day in 1 or 2 divided doses
Colistin	Poorly absorbed	100-300 mg/day in 2 or 3 divided doses	100-300 mg/day in 1 or 2 divided doses
Vancomycin	Poorly absorbed		2 gm/day in 2-4 divided doses
Ristocetin	Poorly absorbed		2-4 gm/day in 2 divided doses
Cephalothin	Poorly absorbed	4-6 gm/day in 4-6 divided doses	2-6 gm/day in 4-6 divided doses

*Oral route not recommended in initial therapy.
†Dosage applicable to chlortetracycline, oxytetracycline, and tetracycline.

staphylococcal drugs, and their potential ability to cause toxic effects will probably continue to militate against their more widespread use.

As a generalization, antibacterial therapy of bacteremia due to staphylococci, like that due to most other bacterial strains, should be continued until the patient has been afebrile for at least 72 hours and three successive blood cultures have been negative.

Streptococcal Bacteremia

This condition has been studied by members of our group,[1] and a group A beta-hemolytic streptococcus organism *(Streptococcus pyogenes)* was responsible in about 50% of cases. Group D streptococci or enterococci, such as *S. faecalis,* were causative in about 30% of cases, whereas alpha-hemolytic or viridans streptococci, such as *S. mitis* and *S. salivarius,* were largely responsible in the remainder. Bacteremia due to anaerobic and microaerophilic strains of streptococci is infrequent.

In the treatment of bacteremia due to *S. pyogenes,* some workers give one million units of benzyl penicillin intramuscularly or by intermittent intravenous injection every four to six hours; other workers give larger amounts of the drug by continuous intravenous administration. In bacteremia due to *S. mitis* and kindred organisms, my colleagues and I are currently investigating a regimen of 1 gm of streptomycin given intramuscularly, plus 20 million units of benzyl penicillin given intravenously, per day; but some workers believe that streptomycin is not required in these infections. Because most strains of enterococci and anaerobic and microaerophilic strains of streptococci are more resistant to penicillin G than are other streptococci, we usually institute the same regimen outlined for infection due to *S. mitis* and allied organisms and increase the amount of benzyl penicillin in increments of 10 million units until the serum bactericidal test reveals total killing in a dilution of one to four or greater. In enterococcal bacteremia, some workers prefer kanamycin to streptomycin. There are preliminary indications that ampicillin may be as effective as streptomycin-penicillin G as an anti-enterococcal regimen. An amount of 6 gm or more of ampicillin should be given daily by a parenteral route, preferably intravenously; streptomycin or kanamycin may further enhance the effect of ampicillin.

In patients allergic to the penicillins, such antibiotics as cephalothin, erythromycin, lincomycin, or a tetracycline may be applicable in cases of bacteremia due to *S. mitis* or kindred organisms. These drugs, excepting the tetracyclines, are also considered in bacteremia due to *S. pyogenes;* about 40% of strains of *S. pyogenes* resist the action of the tetracyclines. A considerable number of enterococci and anaerobic and microaerophilic strains of streptococci resist the action of the alternative drugs, and the physician may have to rely on such antibiotics as vancomycin or ristocetin.

Pneumococcal Bacteremia

In cases of pneumococcal bacteremia, penicillin G is the drug of choice; the route of administration and daily amount, which may be several million units, are dependent in part on the presence or absence of associated endo-

TABLE 3

Classification of the Family Enterobacteriaceae*
(Adapted From Edwards and Ewing)[14]

Tribe	Group
Escherichieae	*Shigella*
	Escherichia (*E. coli,* including *Alkalescens-Dispar*)
Salmonelleae	*Salmonella*
	Arizona
	Citrobacter (formerly *E. freundii* and including *Bethesda-Ballerup*)
Klebsielleae	*Klebsiella*
	Enterobacter (formerly *Aerobacter*)
	E. cloacae
	E. aerogenes
	E. liquifaciens
	E. hafniae (alvei)
	Serratia
Proteeae	*Proteus*
	P. mirabilis
	P. vulgaris
	P. morganii
	P. rettgeri
	Providence
	P. alcalifaciens
	P. stuartii
Edwardsielleae	*Edwardsiella*
	E. tarda

*The term "paracolon" or paracolobactrum is not found in this classification; organisms in this group are assigned positions among the Enterobacteriaceae as follows: *P. aerogenoides* as *Enterobacter hafniae; P. intermedium* as *Citrobacter* group; *P. arizoneae* as *Arizona* group; *P. coliforme* as *E. coli;* and Paracolon 29911 or *Proteus inconstans* as *Providence* group.

carditis or meningitis. In patients allergic to the penicillins, a drug such as cephalothin, erythromycin, or lincomycin may be given. Because some strains of pneumococci are resistant to the tetracyclines, use of these drugs in pneumococcal infections, without in-vitro susceptibility tests indicating their applicability, may be hazardous.

Neisserian Bacteremia

This type of bacteremia is most commonly due to *Neisseria meningitidis,* the management of which is virtually inseparable from that of meningococcal meningitis. Benzyl penicillin in amounts of one million units every two to four hours by intramuscular injection may be used, but even larger amounts have been given per day intravenously. Because a number of strains of meningococci are resistant to the sulfonamides, these drugs cannot be relied on for initial management. *N. gonorrhoeae* rarely succeeds in invading the bloodstream, but large doses of penicillin G are recommended if invasion does occur.

Bacteremia Due to Gram-Negative Bacilli

This condition is most frequently due to organisms belonging to the family Enterobacteriaceae. In Table 3 there is a classification of the Enterobacteriaceae, adapted from Edwards and Ewing.[14] If the biochemical methods advocated by Edwards and Ewing are employed for isolating, grouping, and, in many cases, identifying members of the Enterobacteriaceae, differences will be found in the incidences of individual pathogens on comparison with those found in older studies based on other classifications. However, these differences are minimal and should not result in significant problems. Douglas and coworkers[15] have contributed helpful data regarding the laboratory diagnosis of infection due to the Enterobacteriaceae.

The comparative incidence of bacteremia due to *Shigella* should remain unchanged, and *Escherichia* remains the most common causative organism in the family.

The incidence of bacteremia due to *Salmonella* and *Arizona* should not be significantly changed, whereas that due to *Citrobacter* probably will be in the neighborhood of 2 to 3%.

Bacteremia due to the Klebsiella-Enterobacter-Serratia group is second in incidence only to *Escherichia.* Of this group, *Klebsiella* causes about 80% of clinical infections, whereas *Enterobacter* is responsible for approximately 15%, with *Serratia* causing the remainder.

Bacteremia due to *Proteae* is third in incidence, and that due to the Proteus group is far more common than that due to the *Providence* group organisms. Of the *Proteus* group species, the indole-negative *P. mirabilis* causes 70 to 80% of clinical infections, while the indole-positive *P. vulgaris, P. morganii,* and *P. rettgeri* cause the remainder.

Bacteremia due to *Edwardsiella* is rare and probably accounts for less than 1% of cases due to the Enterobacteriaceae.

For convenience, in addition to the Enterobacteriaceae, certain other gram-negative bacilli will be considered at this time (Table 4). These gram-negative bacilli, which are not members of the Enterobacteriaceae, are being considered concurrently, because antibacterial therapy when given empirically must be designed with these additional bacilli in mind. Bacteremia due to *Pseudomonas,* in recent years, has gradually attained an over-all incidence higher than that due to *Proteus* in some institutions. The other pathogens listed in Table 4 are not common causes of bacteremia, but a special word appears in order regarding bacteremia due to *Bacteroides.* Failure to obtain anaerobic cultures of the blood may conceal the fact that bacteremia due to *Bacteroides* may be present. In two thirds of our patients with such bacteremia, incubation times ranged from five to 20 days.

Before consideration is given to possible antibacterial regimens that may have empiric

use in patients about whom knowledge of in-vitro inhibition tests is lacking, it may be well to discuss those drugs to which gram-negative bacilli are most likely to be susceptible on the basis of current data. As aforementioned, cephaloridine is not recommended for use unless in-vitro inhibition tests indicate its applicability; consequently, it will not be considered herein as a potential empiric regimen.

Shigellosis, unlike salmonellosis, almost always is a solely intraluminal enteric infection; however, about 50 cases of *Shigella* bacteremia have been documented to date. Because of increasing drug resistance of *Shigella,* ampicillin, a polymyxin (polymyxin B, colistin), kanamycin, or chloramphenicol may be applicable.

As a generalization, *Escherichia* organisms are susceptible to streptomycin and to the tetracyclines in about 50% of cases. Cephalothin inhibits about 70% of *Escherichia* organisms. These bacilli are susceptible to ampicillin, a polymyxin, kanamycin, or chloramphenicol in 80% or more of cases.

In regard to bacteremia due to *Salmonella typhi:* whereas chloramphenicol continues to be favored over ampicillin by some workers because of the more rapid control of fever and early symptoms, there are some data indicating that the use of ampicillin may result in fewer relapses. In bacteremia due to other *Salmonella* or *Arizona,* ampicillin, kanamycin, a polymyxin, or a tetracycline may be preferable. In *Citrobacter* bacteremia, a polymyxin, kanamycin, tetracycline, or chloramphenicol usually is indicated on in-vitro studies.

Of the Klebsiella - Enterobacter - Serratia group, *Klebsiella* organisms are most likely to be susceptible to the available antibiotics. Since *Klebsiella* organisms cause about 80% of clinical infections due to this group, this is a fortunate occurrence. As a generalization, strains of *Klebsiella* are susceptible to streptomycin, the tetracyclines, and ampicillin in 20 to 30% of cases; these bacilli are susceptible to chloramphenicol, kanamycin, the polymyxins, and cephalothin in approximately 80% of cases. Whereas a few exceptions occur, Enterobacter organisms are susceptible only to the polymyxins and kanamycin, and the susceptibility of *Serratia* bacilli is virtually restricted to kanamycin.

Among other drugs, penicillin G, ampicillin, cephalothin, novobiocin, kanamycin, and chloramphenicol are effective against *P. mirabilis.* Whereas cephalothin and chloramphenicol may prove active against certain indole-positive *Proteus* organisms and *Providence* bacilli, as a generalization, kanamycin is the drug of choice against these pathogens.

Edwardsiella organisms may be sensitive to several antibiotics, including the tetracyclines, chloramphenicol, kanamycin, and ampicillin.

In *Pseudomonas* bacteremia, a polymyxin is the preferred drug. In *Mimeae* bacteremia, a tetracycline combined with either kanamycin or a polymyxin is the regimen of choice. Despite the availability of newer drugs, a tetracycline generally is preferred in bacteremia due to *Bacteroides* organisms; chloramphenicol is also effective against these organisms; penicillin G and cephalothin may be active against certain strains of *Bacteroides.*

With these data in mind, the application of empiric antibacterial regimens in the management of bacteremia due to gram-negative bacilli can be considered.

Empiric antibiotic therapy is initiated on receipt of reports of blood cultures positive for gram-negative bacilli, or when bacteremia is likely after blood has been drawn for culture. In the past, a tetracycline combined with streptomycin, or alternatively, chloramphenicol and kanamycin, has been the preferred regimen under these circumstances by members of our group. More recently we have been investigating the combined use of cephalothin and a polymyxin. Other possible empiric regimens that may warrant investigation are cephalothin plus kanamycin and ampicillin given with kanamycin or a polymyxin.

In cases of bacteremia likely due to gram-negative bacilli, empiric administration of these regimens is preferred, because definitive microbiologic data will not be available for one or more days, and the broader antibiotic coverage is desirable. There is no dispute regarding the generalization that best results are obtained when the infecting bacilli are susceptible on in-vitro tests to the antimicrobial drugs employed, but the difficulty lies in

the unavailability of such data when the clinical status of the patient makes initiation of therapy necessary.

Empiric use of combined antibiotic therapy is not without disadvantages. These include the dual depressive effect on the gram-negative elements of the flora, making superinfection more likely. However, periodic study of the sputum and stools during therapy may reveal any floral changes and impending clinical superinfection. Streptomycin, kanamycin, the polymyxins, and possibly cephalothin are potentially nephrotoxic; excepting cephalothin, these drugs may cause a curariform effect that is manifested by respiratory depression and cardiac arrest. Chloramphenicol is hematotoxic. Streptomycin and kanamycin are ototoxic, but the latter is more likely to cause deafness. The polymyxins may also cause cerebellar ataxia and other neurologic complications. Ampicillin can cause anaphylaxis and the other untoward reactions characteristic of the penicillins and induces superinfection in about 5% of patients. Like ampicillin, cephalothin may induce superinfection from *Pseudomonas, Enterobacter, Bacteroides,* and sometimes other organisms. It appears unwise to employ drugs in combination, which share a significant toxic effect, because such use may enhance the likelihood of occurrence of such toxicity. As an example of this, kanamycin combined with a polymyxin might enhance the likelihood of a curariform reaction or a nephrotoxic effect.

With the advent of newer drugs, my colleagues and I have reevaluated our policy of employing combined antibiotic therapy. A polymyxin is inadequate as a single agent because *Serratia, Proteus, Providence,* and *Bacteroides* organisms are usually resistant to these drugs. Kanamycin has the disadvantage that a number of *Pseudomonas* and most *Bacteroides* are insensitive to it. Ampicillin is inactive against most *Klebsiella-Enterobacteria-Serratia* organisms, most *Proteus* bacilli that are indole-positive, most *Providence* bacilli, and *Pseudomonas* organisms. Cephalothin is not active against *Enterobacter-Serratia* organisms, many *Bacteroides,* most indole-positive *Proteus* and *Providence* bacilli, and is usually inactive against *Pseudomonas.* To date there is no single drug available that assures complete "coverage" against gram-negative bacilli.

Except for *Pseudomonas* organisms, the chloramphenicol-kanamycin regimen gives excellent "coverage" against gram-negative bacilli, whereas cephalothin, when combined with a polymyxin that remedies this defect, gives less assurance that indole-positive *Proteus* organisms, *Providence* bacilli, and *Bacteroides* organisms are being effectively covered. Consequently, if there are special reasons to suspect that the pathogen is *Pseudomonas*—for example, in patients having underlying hematologic disease—a regimen containing a polymyxin is to be preferred. Also it is to be recalled that the chloramphenicol-kanamycin regimen is potentially more toxic than cephalothin combined with a polymyxin.

Clostridial Bacteremia

This may occur in patients with underlying hematologic disease and in those with neoplastic disease; but most such infections have been associated with postabortal or puerperal sepsis. Placing the patient in a hyperbaric chamber is essential. Penicillin G in massive doses is the antibacterial drug of choice, but some workers believe that a tetracycline also should be given. Surgical extirpation of a septic focus, blood transfusions, and polyvalent gas-gangrene antitoxin may also be considered.

Listeria Bacteremia

Although this type of bacteremia may complicate neoplastic disease and diabetes mellitus, it has a propensity to occur during pregnancy. Infection due to *Listeria monocytogenes* may cause bacteremia in the infant while the mother is asymptomatic or has had an influenza-like illness. Penicillin G, erythromycin, or a tetracycline is recommended.

Summary and Conclusions

Antibiotic therapy is begun empirically when report of blood cultures is received, or, in seriously ill patients, after blood is drawn for cultures. If the patient's condition and microbiologic data later indicate that such empiric therapy is unsatisfactory, it is modified accordingly. Use of specific antibiotics in the initial management of these patients is only theoretically possible because, practically, one

is often thwarted by lack of cultural proof of the pathogen and, almost always, of its in-vitro susceptibilities. However, these difficulties are not of such magnitude that the physician cannot devise adequate antibiotic therapy on an empiric basis. If such a regimen is not employed, or not employed early in the infection, the essential problem is not being attacked, and recovery is unlikely.

It should be emphasized that the physicians must guard against losing valuable therapeutic time while awaiting the results of laboratory procedures and belatedly diagnosing bacteremic shock when the patient has not responded to regimens more pertinent to noninfectious shock. If bacteremic shock is not diagnosed early and if adequate antibiotic therapy is not quickly initiated, no supportive treatment will have optimal effect.

Heart Diagnosis in Ancient Egypt

When his Heart spreads out, behold the vessels of the Heart are with excrement.

When the Heart is sick, behold there is an Oppression of the Heart, or it is an Overflow of Blood which arises in the Heart. It falls down and approaches his diaphragm, while his Heart feels an aversion.

When his Heart is in its right place the Fat of the Heart is on the left side. It neither rises upwards nor falls downwards. It remains soundly in its place.

When his Heart trembles and there is much fat under his Left breast, behold it is his Heart which causes a little of the sinking because his disease is spreading.*

How Are You?

Don't tell your friends about your indigestion:
"How are you!" is a greeting, not a question.
—Arthur Guiterman

Pediatrics

The Battered Child Syndrome

Part 1—Medical Aspects

PREVENTION AND reporting of "battered" children are obviously important, but recognition of such cases by the physician remains an important first step in the institution of appropriate action. Our purpose is to aid the physician in the recognition of children who have been traumatized or neglected and who fall within the scope of the "Battered Child" laws. The cases presented here describe a spectrum of physical abuse from over-zealous spanking to infanticide, that have come to the attention of the authors since 1963, when the Minnesota "Battered Child" law was passed.

Table 1 presents a summary of eighteen cases. The patients in all but two cases were under age three. The assailant was presumed to be the parent in fourteen of eighteen of the cases. The clinical diagnoses ranged from "failure to thrive", rickets, multiple ecchymoses, burns, lacerations, dehydration, vomiting, diarrhea, multiple fractures, subdural hematomata, blindness, deafness, and seizures. Three of the eighteen children died as a direct result of physical abuse; ten had a previous history of assumed beating or physical neglect.

Worthy of special note for the recognition of such cases is that in sixteen of the eighteen children the history initially obtained was incompatible with the physical findings; and despite the frequent intimation that the lesions were spontaneous, no new lesions occurred while any of the patients were in the hospital.

Discussion

Incidence

Because of lack of recognition and/or failure of reporting, the real incidence of the syndrome is unknown. Retrospectively, the American Humane Association says there are over 10,000 such cases per year. In a prospective study, Holter and Friedman,[1] on two separate surveys, found that 10% of all children seen in an emergency room for injuries during given periods of time were victims of physical abuse. In New York City, over a one-year period, 706 cases of the "battered child" syndrome were reported.[2] It seems fair to assume that the incidence is probably much higher than the figures usually given.

Characteristics of Maltreatment

In many of the cases of maltreatment certain characteristics are present (Table 2). Most important of these is evidence of trauma which is disproportionate to the history given. The child with burns (especially cigarette burns), dislocations, fractures (often multiple), of the long bones—particularly if the trauma is in different stages of healing—should alert the physician to the likelihood of abuse. Often in addition to the causes of the trauma being historically vague, there is a history of previous episodes similar to the one with which the physician is presented. Of importance is that no new lesions occur after removal of the patient from the home environment. The patient is usually less than three years old. Other findings often present are poor nutrition, poor skin hygiene, irritability, and repressed personality. In Holter and Friedman's series[1] ingestions were commonly associated with the maltreatment syndrome.

Varieties of Abuse

The varieties of abuse and neglect range from food deprivation or a severe spanking to homicide. Usually only one child in the

TABLE I

Age *Race/Sex* *Chief Complaint*	*Past History*	*Findings*	*Assailant and Result*
3* years Negro/ Male "He was beaten"	Negative	Ecchymoses on left forehead, eye, thigh	Stepfather Cleared
14 years Caucasian/ Female "I was beat up"	Negative	Ecchymoses on face, upper arm	Mother's boyfriend Cleared
1 year Indian/ Female "Fever and cough for five days"	Removed once before because of "neglect", one sibling beaten	Ecchymoses over nose, under each eye; pneumonia; failure to thrive; recent fracture right tibia; abnormal EEG	Mother Improved, became very outgoing
5 years Indian/ Female Abandoned	Past history of being burned by mother when drunk. ER visits for pneumonia sibling of 5 and 6.	Granulation tissue; infected lesions scalp, finger, feet, pneumonia	Mother Resolved
3 years Indian/ Female Abandoned	Multiple ER visits, one for coat hanger injury to eye, another for fall down stairs sibling of 4 and 6	Cigarette burns on thighs; infected skin lesions	Mother Resolved
1 year Indian/ Female Abandoned	Sibling of 4 and 5 with past history of anemia and growth retardation	Multiple excoriations: scars, ulcers, ecchymoses on shoulders; anemia	Mother Resolved
1½ years Caucasian/ Male "Burn"	Admitted one week before secondary to too severe a spanking. Mother said she "lost control."	20% second degree burns from being held under a faucet of hot running water	Mother Burns healed
5 months Caucasian/ Female "Fell from chair"	Fracture of femur at 2 months; apneic episode of 45 minutes; no M.D. seen	Pale; skull had widened sutures; positive right subdural tap; seizures; retinal hemorrhages and decreased weight	Mother and father Resolved
17 months Caucasian/ Female "Diarrhea and vomiting"	URI, diarrhea	Numerous bruises, soft tissue swelling forehead, scratches over left cheek; dehydrated; otitis	Unknown Resolved
8 months Caucasian/ Male "Not gaining weight"	One previous admission; pin in uretera	Rickets, hematomata left thigh, swelling both arms, swelling right side skull fracture, fracture right ulna, fracture left humerus, fracture right acromion	Both parents Gained weight, developed mentally, gained milestones, rachitic rosary and thickened wrists disappeared, fractures healed.

TABLE I (Continued)

Age *Race/Sex* *Chief Complaint*	*Past History*	*Findings*	*Assailant and Result*
1½* years Caucasian/ Male "He woke up bleeding"	Three previous hospitalizations; multiple fractures, bruises, subdural	Lacerated scalp linear, punctate wounds on both feet, ecchymoses on face	?Both parents —probably mother Lesions healed
6 months Caucasian/ Male "Fell out of crib"	Police called to home one week prior to admission because neighbors complained that mother was beating the child	Fractured skull, subdural ecchymoses of face, lacerated lip	Father Craniotomy, resolved
1 month Caucasian/ Female Seizures, cyanosis, vomiting	Other siblings battered	Positive subdural taps; irritable hydrocephalic	Unknown Shunt
2 months Caucasian/ Male "Vomiting and sleepy"	Negative, one other sibling removed secondary to beatings	Parietal eggshell skull fractures, subdurals, hydrocephalus, cortically blind and deaf	Mother Craniotomy, blind and deaf
2 years Caucasian/ Male "Fell down stairs"	Negative	Distended abdomen, paracentesis milky bile fluid	Father Surgery—infarcted liver from trauma
1¾ years Caucasian/ Female "Vomiting: not gaining weight"	Subdurals, assymetry of head, papilledema, eye ground hemorrhage; hydrocephalus; development retarded; x-rays showed no fractures, long bones; craniotomy evacuated, subdurals	Marasmic; hemorrhagic mouth, head and trunk; ecchymoses of leg; optic atrophy; blind; serum sodium 191 perustical elevation in right tibia, right humerus 3 weeks old; seizures	"Struck by sibling" Died in spite of treatment; at autopsy: skull fracture, hemorrhage, old subdural psoas abscess
4 months Mexican/ Female "Unconscious"	Negative	Skull fractures; subdurals	Unknown—Had been in three foster homes in one week. Died
16* months Negro/ Male "He fell out of his highchair"	NIL—Sibling brought in this year—battered	Opistotonic; dilated right fixed pupil; right anterior forehead covered with bruises; ecchymoses over posterior scalp, right upper quadrant of abdomen; abrasions nose and neck; linear ecchymoses right arm; bruises from scapulae to popliteal spaces; papilledema and hemorrhages in eye	"Aunt" Craniotomy—died

*See Case Reports

family is the target; but by no means is this always the case. (Of interest here is that three cases (Table 1) were all from one family, yet a fourth sibling was completely spared.) Hairbrushes are a common instrument used to inflict physical abuse; but fists, straps, electric cords, TV aerials, ropes, rubber hoses, fan belts, sticks, bottles, broom handles, baseball bats, chair legs, paring knives, and screwdrivers are also employed. These children are also submitted to burns, strangling, suffocation, stabbing, biting, shooting and electric shock. They may be violently thrown, with arms and legs used as handles. Cases have been reported where pepper was stuffed in the pharynx, suffocating the victim.[3] One child was reported to have been buried alive.[3] Attempts have even been made to burn the corpses of the battered children.

In a series of autopsies,[5] the causes of death listed included starvation, burning, gunshot wounds, asphyxia secondary to ligature, drowning, smothering, and carbon-monoxide poisoning. Also listed were stabbing, chopping with an ax, pounding with a hammer, and "squeezing to death." Almost all deaths have occurred in the home.

The "battered child" syndrome should be considered in all cases of childhood death where there is inadequate explanation for the extent of injury, or where the clinical picture is bizarre. Although the history most often obtained sounds outwardly reasonable, such as an accidental fall from a crib, table or sofa, accidental dropping during bathing, suffocation in the crib, and aspiration and assault by siblings, nevertheless the location, extent and type of injury incurred is unusual or improbable, considering the accident described. Also, a child is frequently brought to the physician with only a history of vomiting, fever or cough; lethargy or poor weight gain, with no explanation for obvious trauma.

TABLE 2

When to Consider a Diagnosis of Maltreatment

Subdurals
Bruises, cuts, abrasions disproportionate to the history
Burns—especially cigarette
Dislocations
Fractures, often multiple—especially of long bones
Above in *different stages of healing*
Causes of trauma in question
History of previous episodes
No new lesions during removal from home
Less than three years old
Failure to thrive
Poor skin hygiene
Irritability
Repressed personality
Ingestions

Differential Diagnosis

The major differential diagnoses in cases of multiple or recurrent fractures include osteogenesis imperfecta, hypophophasia, hyperuricemia with self-mutilation, scurvy, neonatal syphilis, infantile cortical hyperostoses, sensory deficit or indifference to pain. Other disease possibilities to be considered are rickets, celiac disease, osteomyelitis, bone tumors, blood dyscrasias, congenital coxa vera, meningitis, infectious diarrhea, tuberculosis, congenitally dislocated hip, and poliomyelitis.

Early recognition of the "battered child" and removal from the traumatic environment are of paramount importance for salvage of these patients, since the rule, rather than the exception, is that the patient will return, either further traumatized or dead. In one series, 10% returned dead. Other series report recurrent trauma in 30 to 50% of children.

Case Reports

Three cases are reported here to illustrate the range of injuries sustained by the "battered" children.

Case 1

A three-year-old negro male was admitted to Hennepin County General Hospital in February 1968 with a chief complaint by his mother that he "was beaten." His mother, a University of Minnesota student, was away from home at the time, leaving him in the care of his Caucasian stepfather. In response to being told to go to bed the patient defecated in his clothes and was then allegedly beaten by his stepfather. Physical examination revealed ecchymoses over the anterior forehead, the left eyelid, and both anterior thighs. X-rays of the skull and long bones were negative. There was no past history of beating.

Case 2

An eighteen-month-old Caucasian male was admitted to the University of Minnesota Hospitals in September 1967. Significant past history revealed that at 2½ months of age he had been admitted to a hos-

pital in Minneapolis with a seizure disorder. A diagnosis of bilateral subdural hematoma had been made and a craniotomy performed. Long-bone x-rays at that time had revealed periosteal new bone formations of both the left and right femurs and tibias, which were interpreted as evidence of healing fractures. The child's landlady had appeared and informed the attending physician that she and other neighbors had heard beatings going on through the walls.

The child had previously been admitted to the University of Minnesota Hospitals at the age of six months with the chief complaint of dehydration. Also stated in the history was that he had not been eating for three days and had been batting his head on his crib. Physical examination revealed a dehydrated, apathetic, frightened child. Thirty bruises were counted on his head and anterior chest. Scratches were present on his nose and chin; there was blood on his palate and a soft tissue swelling over the mandible. He had poor head control and difficulty in swallowing. (See Figures 1 and 2.) During the interview, it had been noted that the mother had a very flat affect and seemed quite unconcerned, and that the father was quite hostile. (He had previously been jailed for beating the mother.) No new lesions developed during the hospitalization, and the child was released to the custody of the Welfare Department for three months.

He was admitted again in August 1967, at 16 months of age, with the history that "he fell out of his crib," and that three days later he "suddenly" developed a mid-frontal swelling. On physical examination, multiple abrasions, scars, scratches, and bruises about the eyes and on the face were noted. He also showed mental and motor retardation. (Subdural taps done obtained 5½ cc of pink fluid on the right.) Psychological testing revealed a 12-month-old aptitude at 16-month chronological age; an electroencephalogram showed an abnormal sleep pattern with an irregular left frontal focus. No new lesions developed during the hospitalization. He was discharged to the family, but assigned clinic appointments were not kept.

In September 1967, at 18 months of age, he was re-admitted for a lacerated scalp. The history was given that he had been found bleeding in his crib, but the parents "had no idea" as to how he had cut him-

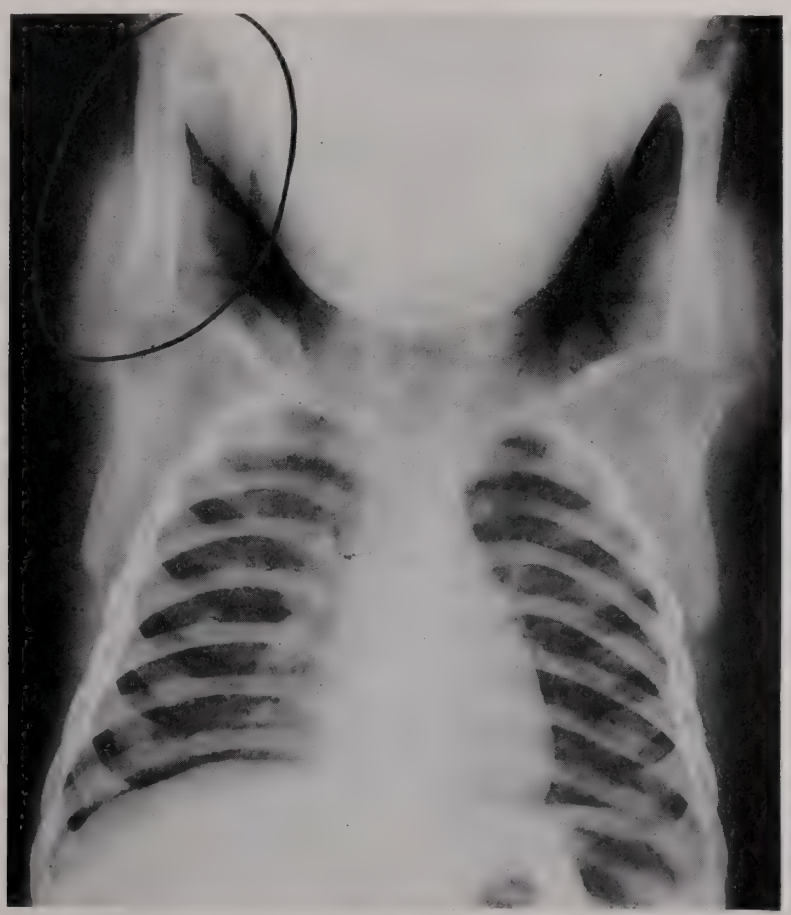

Fig. 1—Roentgenogram of Case 2, at age six months, revealing a healing fracture of the right humerus which is an older fracture than in Figure 2.

self. (They said he was a "head banger"; however, this habit had not been noted in the hospital.) During the interview the parents were very vague and inappropriate. They displayed a marked over-concern for a 2½ year old female sibling who, according to them, had "a high IQ," "never had a mark on her," and "had an emotional breakdown when he (her brother) came home." Physical examination at this time showed a scalp laceration, punctate linear scars on both feet, and a scar on the midback resembling a cigarette burn. Ecchymoses were present on the patient's face and arms.

Case 3

A sixteen-month-old negro male was brought into Hennepin County General Hospital in March 1968 by an "aunt" and a neighbor. The history was that he had fallen three days before and gotten a "bump on his head." He then allegedly resumed normal daily activity but the next day had acted "sleepy eyed." The morning before admission he was reported to have been "fine and ate a good breakfast." After the meal he had been placed on the floor and his aunt had left the room. When she returned, she noted that he was unconscious and unresponsive. The upstairs neighbor suggested that he must have climbed onto a chair and fallen onto his head, as the aforementioned swelling became larger. On further questioning, the aunt admitted that she had "spanked" him with a belt two days prior to admission and "may have hit his abdomen." It was later discovered that the "aunt" had given an alias, as had the neighbor. Both were prostitutes, as was the child's mother who was "looking for work in Indianapolis." Also, the "aunt" had been tried for shooting a boyfriend earlier in the year.

Physical examination showed an opistotonic male with dilated fixed right pupil and hemorrhages in both eye grounds. The left eye was deviated down and out. He responded only to deep pain and he was in extensor spasm. He had old bruises and abrasions over the right anterior forehead, ecchymoses over the posterior scalp, right eyelid and right upper quadrant of the abdomen, abrasions over the nose and scratches on the neck. There were linear ecchymoses over the left lower chest and left abdomen, parallel ecchymoses over the right upper arm, ecchymoses on the right lower arm, and continuous bruises from the posterior leg and popliteal area to the scapulae. Subdural taps could not be done as the sutures were closed; so he was taken to the operating room where trephinations were done bilaterally, with 75 cc of subdural clot being removed from the right. Marked cerebral edema was noted at surgery. He died the morning after admission.

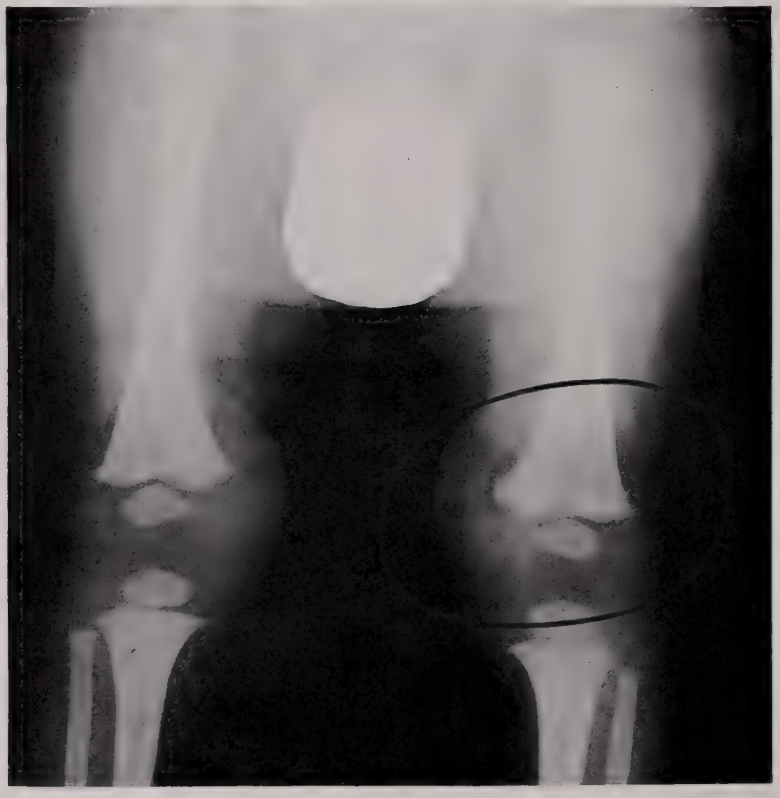

Fig. 2—Recent fracture of left femoral epiphyseal plate, taken at the same time as Figure 1.

Summary

The Battered Child syndrome occurs not infrequently and should be suspected when evidence of trauma is disproportionate to the clinical history. The varieties of abuse can be appalling.

Battered Child Syndrome

A series of articles on the Battered Child Syndrome by Doctors Hugh D. Allen, Robert W. ten Bensel, and Richard B. Raile will be published in the following issues of MINNESOTA MEDICINE.

January—A discussion of the psychological and social aspects with consideration given to the parent, child, and health personnel.

February—Legal aspects will be discussed with emphasis on cases since the changing of the Minnesota State law in 1963. The physician's responsibility (moral and legal) and suggestions for development of a Battered Child law per se will be discussed.

March—A review of the syndrome and discussion of the future of children and the role of physicians.

School of Salerno

When to Bleed

The Heart and Liver, Spring @ Summers bleeding,
The Fall and Winter, hand and foot doth mend,
One veine cut in the hand, doth help exceeding
Unto the spleene, voyce, brest, and intrailes lend,
And swages griefs that in the heart are breeding.
—Regimen Sanitatis Salerni

Editor's note: The School advises that to benefit the heart and the liver, bleed the patient in the spring or summer; for the hands and feet, bleed in the fall or winter. Cutting one vein in the hand benefits the spleen, the voice, the breast, and the entrails; it even mitigates incipient grief.

It's the Law

Primer of Parliamentary Procedure*
The Tactics of Change

A *main motion* having been presented, seconded, and stated by the Chair, the assembly proceeds to act upon it. Discussion of the merit or lack of merit of the recommended action may now take place. Members may discuss and argue their various viewpoints before the society after individual recognition ("obtaining the floor") by the chair. Each member has the right to speak twice on the same question but may not make his second speech until all members who desire to speak for the first time have had opportunity to be heard.

During debate, changes in the *main motion* may be effected by certain *subsidiary motions.* The *main motion* may be altered in part or total by the motion *to amend,* and may take the form, "I move to amend the resolution by inserting the word *very* before the word *good.*" In other forms, the amender may move to "strike out" a certain word or words; to "strike out and insert;" to "substitute."

The motion to *amend* must be seconded and, after being stated in full to the assembly, it too becomes debatable. During discussion, the motion to *amend* may be amended, but only once, since amendments of the third order are cumbersome. After debate on the motion to *amend,* the chair puts the question (The motion to *amend*) and asks for the vote. If the vote is in the affirmative, the *amended* main motion becomes the question before the assembly. If a majority vote "No," the original main motion is again before the group.

A second tactic of change is the motion to *refer* or *commit* the main motion to a standing or special committee or individual. Like the motion to *amend,* the motion to *refer* requires a second, and when stated by the Chair, becomes debatable and amendable. If amended, the amendment is first voted upon, then the motion to *refer.*

At this point in our lesson a brief digression is in order so that we may introduce a discussion of the precedence or priority of motions. We have stated that only one *main motion* may be before the assembly at any time. Yet, in the above paragraphs, several motions have been considered in order. There is then a relationship between various motions providing a key to their individual entry into the parliamentary scheme. Thus, once a *main motion* is before the group, it may be *amended, referred, postponed, laid on the table,* etc. Basic to parliamentary procedure is this priority classification of secondary motions allowing the motion to *amend,* then the motion to *refer,* in that order, but not the reverse. Similarly the motion to *lay on the table* takes priority over to *amend* and to *refer,* and must be considered first by the Chair. Certain special motions such as *to adjourn* take precedence over all other motions and may even be in order when a vote has been ordered on the *main motion.* Time and space do not permit a full description of the priorities of various motions, but any manual of parliamentary procedure will readily produce this classification.

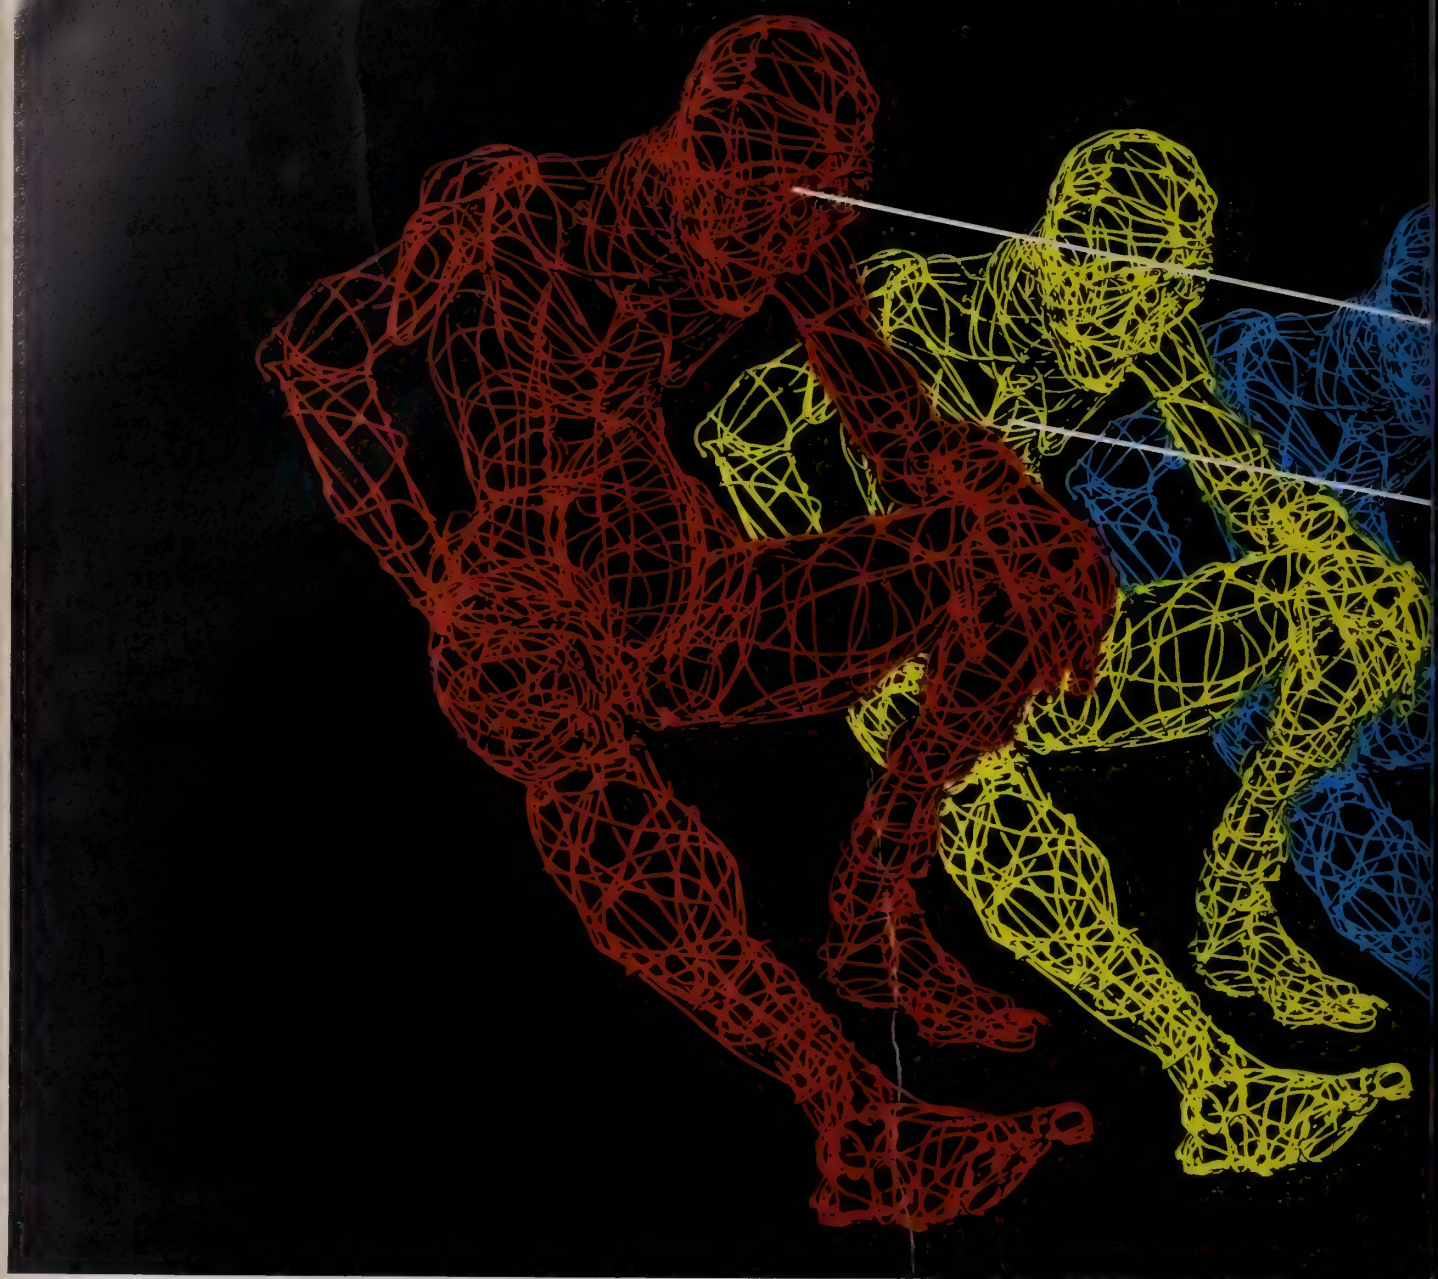
(To be continued next month)

It's going to be fun to watch and see how long the meek can keep the earth after they inherit it.—Frank Hubbard

Dilantin®
(diphenylhydantoin)

PARKE-DAVIS

In untold thousands of epileptic patients... Dilantin has been, and continues to be, the bedrock of therapy.



DILANTIN is useful in the treatment of grand mal epilepsy and certain other convulsive states. Its use will prevent or greatly reduce the incidence and severity of convulsive seizures in a substantial percentage of epileptic patients, without the hypnotic and narcotizing effects of many anticonvulsant drugs.
PRECAUTIONS: Periodic examination of the blood is advisable. Nystagmus in combination with diplopia and ataxia indicates dosage should be reduced. The possibility of toxic effects during pregnancy has not been explored. ADVERSE REACTIONS: Allergic phenomena such as polyarthropathy, fever, skin eruptions, and acute generalized morbilliform eruptions with or without fever. Rarely, dermatitis goes on to exfoliation with hepatitis, and further dosage is contraindicated. Gingival hypertrophy, hirsutism, and excessive motor activity are occasionally encountered. During initial treatment, side effects may include gastric distress, nausea, weight loss, nervousness, sleeplessness, feeling of unsteadiness. Macrocytosis, megaloblastic anemia, leukopenia, granulocytopenia, thrombocytopenia, pancytopenia, agranulocytosis, and aplastic anemia have been reported. Nystagmus, lymphadenopathy, lupus erythematosus, erythema multiforme (Stevens-Johnson syndrome), and a syndrome resembling infectious mononucleosis with jaundice have occurred.
DILANTIN is supplied in several forms including Kapseals® containing 0.1 Gm. and 0.03 Gm. diphenylhydantoin sodium.
Parke, Davis & Company, Detroit, Michigan 48232

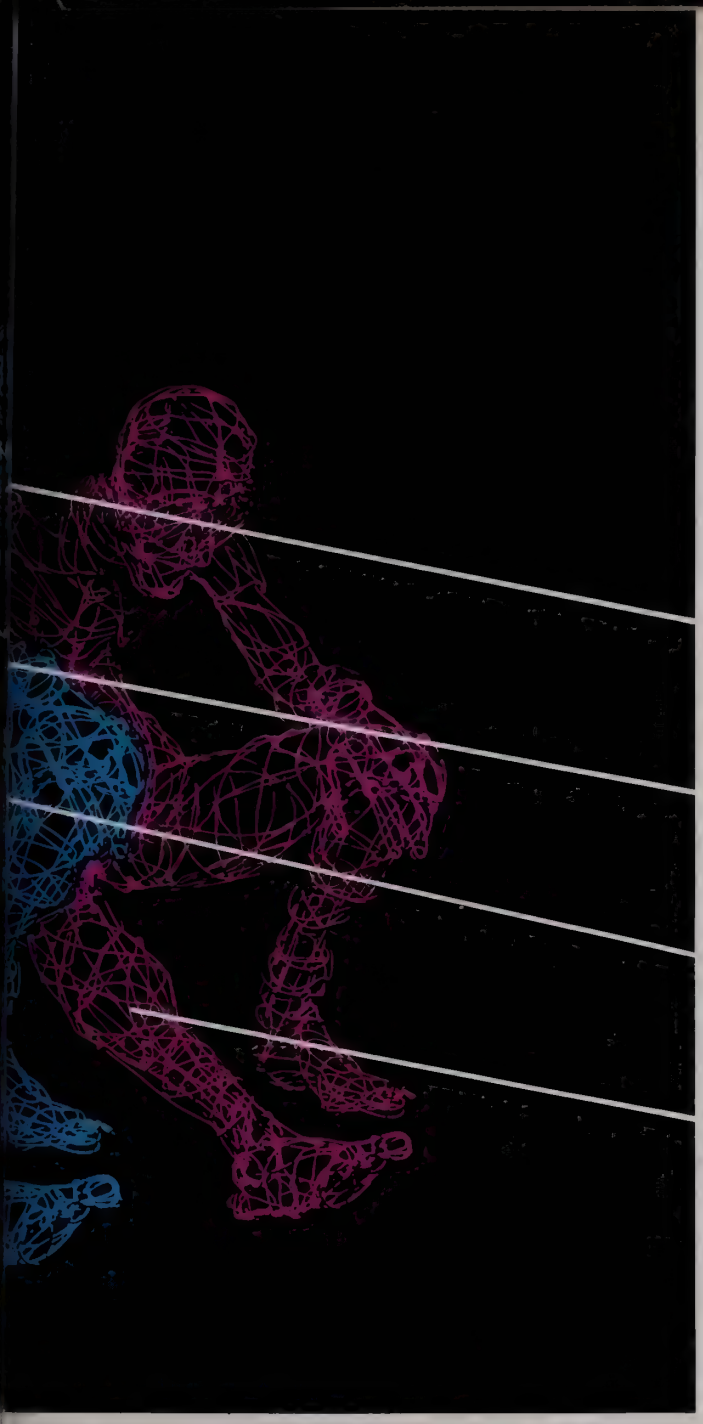
The color combinations of the banded capsules are Parke-Davis trademarks. The orange-banded white capsule identifies Parke-Davis 0.1 Gm. diphenylhydantoin sodium; the pink-banded white capsule 0.03 Gm. diphenylhydantoin sodium.

PARKE-DAVIS 015R67

a comprehensive hematinic

Description: Each Pulvule® contains—

Special Liver-Stomach Concentrate, Lilly (containing Intrinsic Factor)	150	mg.
Cobalamin Concentrate, N.F., equivalent to Cobalamin (The total vitamin B_{12} activity in the Special Liver-Stomach Concentrate, Lilly, and the Cobalamin Concentrate, N.F., is 15 micrograms.)	7.5	mcg.
Iron, Elemental (as Ferrous Fumarate)	110	mg.
Ascorbic Acid (Vitamin C)	75	mg.
Folic Acid	1	mg.



Indications: Trinsicon® (hematinic concentrate with intrinsic factor, Lilly) is a multifactor preparation effective in the treatment of anemias that respond to oral hematinics, including pernicious anemia and other megaloblastic anemias and also iron-deficiency anemia.

Contraindications: Hemochromatosis and hemosiderosis.

Precautions: Anemia is a manifestation that requires appropriate investigation to determine its cause or causes.

In pernicious anemia, the use of folic acid without adequate vitamin B_{12} therapy may result in hematologic remission but neurological progression. Adequate doses of vitamin B_{12} (parenteral, or oral with potent intrinsic factor as in Trinsicon® [hematinic concentrate with intrinsic factor, Lilly]) usually prevent, halt, or improve the neurological changes.

As with all preparations containing intrinsic factor, resistance may develop in some cases of pernicious anemia to the potentiation of absorption of physiological doses of vitamin B_{12}. If resistance occurs, parenteral therapy, or oral therapy with so-called massive doses of vitamin B_{12}, may be necessary. No single regimen fits all cases, and the status of the patient observed in follow-up is the final criterion for adequacy of therapy. Periodic

You can treat combined deficiencies with

Trinsicon®

—the multifactor hematinic

Vitamin B_{12} plus intrinsic factor (15 mcg. B_{12} activity)—helps provide adequate levels of this important vitamin.

Folic acid (1 mg.)—treats nutritional macrocytic anemias and/or malabsorption syndromes.

Ascorbic acid (75 mg.)—augments the conversion of folic acid to its active form and helps iron absorption.

Iron (110 mg.)—treats hypochromic anemia.

clinical and laboratory studies are considered essential and are recommended.

Adverse Reactions: In rare instances, iron in therapeutic doses produces gastro-intestinal reactions, such as diarrhea or constipation. Reducing the dose and administering it with meals will minimize these effects.

In extremely rare instances, skin rash suggesting allergy has followed oral administration of liver-stomach material. Instances of apparent allergic sensitization have also been reported after oral administration of folic acid.

Dosage: One Pulvule twice a day. (Two Pulvules daily produce a standard response in the average uncomplicated case of pernicious anemia.)

How Supplied: Pulvules Trinsicon® (hematinic concentrate with intrinsic factor, Lilly), in bottles of 60 and 500. [032568]

Additional information available to physicians upon request.

Lilly

LOW-BACK PAIN

A CONSERVATIVE, FOUR-POINT PROGRAM

The low back pain that is most frequently seen in general practice is mechanical in nature, i.e., postural back pain, joint dysfunction and acute back strain.[1,2] For this type of discomfort, a conservative regimen is usually sufficient to relieve aches and pains, and to help keep the patient functioning. Components of this basic program include:

1 Bed "If the patient is in the pain-spasm-cycle...there is no alternative or substitute for absolute bed rest..."[3]

2 Board "Boards should be ordered under the mattress...these boards act by immobilizing the spine..."[4]

3 Heat "A very valuable method of applying heat at home is a prolonged hot bath..."[5]

4 Robaxin®-750 (methocarbamol, 750 mg. capsule-shaped tablets) A well-tolerated[6] skeletal muscle relaxant, methocarbamol helps relieve spasm "...without interfering with normal tone and movement."[7] And there is little likelihood of sedation.[6]

Indicated for relief of skeletal muscle spasm. **Contraindicated** in hypersensitive patients. **Side Effects** (lightheadedness, dizziness, drowsiness, nausea) may occur rarely, but usually disappear on reduced dosage. Hypersensitivity reactions develop infrequently. See product literature for further details. **Also available:** Robaxin® Tablets (methocarbamol, 500 mg.) Robaxin Injectable (methocarbamol, 1 Gm./10 cc.)

Grand Rounds

Pulmonary Arteriovenous Fistulae*

ROBERT N. NOTSKE, M.D.
Minneapolis, Minnesota

Historical

Pulmonary arteriovenous fistula is an abnormal communication between the pulmonary artery and the pulmonary vein, anywhere along the course of these structures from the main trunks to precapillary levels. Pulmonary telangiectasiae,† arteriovenous aneurysm, arteriovenous varix, cavernous hemangiomas, cirsoid aneurysms, pulsating angiomas are examples of the terms used to denote this abnormal vascular communication in the lesser circulation.

In the British Medical Journal of 1887 the following report appeared: "Doctor Churton showed the lungs from a boy 12 years of age in whom a loud roaring pulmonary systolic bruit and very highly accentuated second sound were present during life, with haemoptysis, epistaxis and dropsy. Four of the secondary branches in one lung, and three in the other, led to aneurysms as large as walnuts, filled with blood clot. . . ."[1] This is the first known description of a pulmonary arteriovenous fistula, but Churton did not appreciate the nature of the defect, calling it "multiple aneurysm of the pulmonary artery."

In 1917 Wilkens[2] gave a complete description of the clinical and autopsy findings in a sixteen-year-old girl with multiple pulmonary arteriovenous fistulas, but he also called it "a case of multiple pulmonary aneurysms." He described the epistaxis, cyanosis, dyspnea, clubbing of the fingers and toes, and telangiectasiae of the lips and tongue. There were murmurs in both axillae, and the chest x-ray showed densities in both lung fields. Wilkens demonstrated by dissection and injection multiple pulmonary arteriovenous fistulae of both lungs, one of which had ruptured into the pleural cavity. It

*Presented as a Medical Grand Rounds at Hennepin County General Hospital, January 16, 1968.
†See Test Your Word Score Page 1757.

should also be noted that this patient had hereditary hemorrhagic telangiectasiae.

Hemorrhagic telangiectasiae had been described in 1886 by Legg, and in 1887 by Chiari. It was Rendu in 1896 who first associated the tendency toward epistaxis with telangiectasiae occurring in families as a clinical entity.[3] In 1901 Osler[4] presented three cases of recurring epistaxis associated with multiple telangiectases of the skin and mucous membrane, and stated that Babbington and Rendu[3] had previously reported such cases. A few years later Weber[5] followed with further descriptions from his experience. This entity was thus termed "Osler-Weber-Rendu syndrome." Though the first cases of pulmonary arteriovenous fistula and many since were described as having telangiectasia of the mucous membranes and skin, they are not necessarily associated. The relationship between Osler-Weber-Rendu syndrome and pulmonary arteriovenous fistula is present in one third to one half of the cases described in the literature.[6]

The first case of arteriovenous fistula of the lung diagnosed clinically was reported in 1937 by Smith and Horton.[7] The patient was a forty-seven-year-old man who had complained of attacks of numbness, dizziness, convulsions and exertional dyspnea. He had been a "blue baby." Cyanosis and clubbing of the fingers and toes had been noted at twenty-three years of age while he was in the army, and again at forty years of age at the Mayo Clinic. He had been diagnosed as having polycythemia vera and treated with phenylhydrazine and by venesection without benefit. Chest x-ray revealed an abnormality in the base of the right lung, and a continuous murmur was heard over the lesion. Angiograms revealed that the density was vascular in nature.

The first patient with pulmonary arteriovenous fistula cured by operation was reported by Hepburn and Dauphine in 1942.[8] This twenty-three-year-old lady had been diagnosed as having a "leaky valve" in 1932, and in 1938 had been sent to a tuberculosis sanitarium for symptoms referable to the lung. She had also complained of dizziness, faintness, thick speech earlier in life. Chest x-ray disclosed a right lower lobe density. She also was noted to have clubbing, cyanosis, and polycythemia. Artificial pneumothorax was performed with no improvement. A right pneumonectomy was also performed, and the right lower lobe was found to contain a "cavernous angioma." A year later she was asymptomatic; the clubbing of the fingers and toes had receded; and she was pregnant and doing well.

Since that time many other cases have been reported and many successful resections recorded. In 1959 Bosher[9] reported 350 cases, 252 from the previous literature, with 98 new ones. In the interim the reports have dealt with more advanced techniques for diagnosis and more sophisticated techniques for resection.

The experience at Hennepin County General Hospital over the past ten years has resulted in two cases of pulmonary arteriovenous fistula. In the past five years there has been only one case. This patient was seen here this year.

Case Report

A 19-year-old Negro, separated, mother of four, was brought to the Emergency Ward because of the acute onset of a feeling that she was unable to move her legs. This lasted only a few minutes, and by the time she had arrived in the Emergency Ward she was totally asymptomatic. She had also noted a recent dry cough and easy fatigability. There had been no chills or fever. Her past hospitalizations had been for delivery of her children, and two months previously in a private hospital for "nerves." A chest x-ray disclosed a 4-cm. coin-

shaped lesion with a central clear area, located in the posterobasal segment of the left lower lobe. Physical examination was within normal limits.

Repeated sputum smears and cultures, skin tests, and chemical, hematological, and serological studies were within normal limits. Repeated chest films and planigrams showed no change in the lesion, which seemed to expand and contract with respiration. Three days after admission she noted another spell of not being able to move. A nurses' aide noted she had no obtainable pulse or blood pressure and that she appeared cyanotic. Within five minutes she had fully recovered. An electrocardiogram taken at this time disclosed depressed ST-T segments across the anterior precordium, and also in leads 2, 3, and aVF, with a depressed T in aVL. Ten days after admission her cardiogram disclosed non-specific ST-T changes in leads 2, 3, aVF, and now symmetric T wave inversion across the anterior precordium suggesting epicardial ischemia. These changes slowly reverted to normal over a six-week period. She had had similar, though less marked changes, one year previously just prior to her last delivery. A murmur could now be heard both in systole and diastole at the medial portion of the left base. Hgb. was 14 gm., with a normal white blood cell count and differential. Sedimentation rate ranged between 40 and 60 mm/hr. antistreptolysin titres, C-reactive proteins, lupus erythematosus clot tests, cold agglutinins, and viral studies, were within normal limits. Arterial oxygen tension ranged at rest between 50 and 60 mm. of Hg., and did not correct after breathing 100 per cent oxygen for fifteen minutes. After waiting for the electrocardiogram changes to return to a more normal pattern (eight weeks) a cardiac catheterization was performed. All pressure measurements were within normal limits. Angiocardiography disclosed a right-to-left shunt from the pulmonary artery to the pulmonary vein in the posterobasal segment of the left lower lobe. The coronary arteries appeared normal.

A thoracotomy was performed and revealed a large saccular, abnormal vascular communication. A segmental resection was performed. Postoperatively the patient developed a right-sided hemiplegia with aphasia. She has since recovered good motor function, but at this time is still aphasic.

Pathology

The wide variability of anatomic presentation of these pulmonary vascular abnormalities reveals that[9,10] on the one extreme, there may be multiple minute arteriovenous fistulae distributed through all lobes of both lungs, and on the other extreme, a single large saccular communication which often produces marked clinical manifestations. There may be a wide range of minute, small, or large fistulae, scattered or localized, in some instances producing little clinical difficulty, and in others marked symptoms. The configuration of the lesions varies considerably. The large size of the sac is often impressive, particularly when single, and the feeder vessels are usually limited to one or two large arteries.[9] "The channel is often sinuous and may be partly filled with clots. The arteries are usually thin-walled and dilated. The wall is often paper-thin, built up by hyalinized fibrous tissue, elastic fibers and remnants of smooth muscle cells. The intima may be unevenly thickened, partly covered by mural thrombi, and may show atheromatous lesions which are not uncommonly calcified."[10] In other instances, however, convoluted masses of dilated thin-walled vessels with multiple communications dominate the picture. In occasional instances an entire segment and even a lobe may be largely infiltrated and replaced by the pathologic process. "Cases have been described in which a varix of thin-walled vessels spreads out over the surface of the lung like a Medusa head."[9]

Pathogenesis

Pulmonary arteriovenous fistulae are frequently associated with other vascular anomalies. As previously mentioned, one third to one half of the cases in the literature have been associated with hereditary hemorrhagic telangiectasia. Some investigators still believe that the pure pulmonary form may represent a *forme fruste* of the systemic disease. "Pulmonary arteriovenous fistulae may be either acquired or congenital in origin, the latter being much more frequent than the former."[6] The occurrence of a congenital lesion may

be readily explained by the aberrant development of arteries and veins from a common capillary plexus. Although frequently not apparent at birth, these lesions tend gradually to increase in size as a result of inadequate vascular wall formation and constant exposure to direct pulmonary artery pressures. The origin of acquired fistulae, however, is much more complex.[6] Usually no known stimulus has been identified. A recent report described multiple pulmonary arteriovenous fistulae believed secondary to metastatic carcinoma of the thyroid.[11] Other reports have suggested acquired fistulae from pulmonary schistosomiasis[12] and long-standing hepatic cirrhosis.[13]

Distribution

Tables 1 through 4 summarize the anatomic distribution of pulmonary arteriovenous fistulae in 328 cases described by Bosher.[9] Sixty-four per cent were thought to have single lesions. The higher percentage of patients with single lesions reflects the detection of relatively asymptomatic and acyanotic patients through routine x-ray examination.

In Table 3 the cases are listed according to the number of lesions reported per case. Sixty-eight are categorized as "multiple" or "not specified" because of vague or indefinite description. The majority of this unspecified group, however, undoubtedly had more than three lesions. In 30 cases of the entire group of 117, no more than two lesions were found.

TABLE 1
Number of Cases*

Single arteriovenous fistula	212
Multiple arteriovenous fistulae	117
Total cases	328

*From Bosher et al., Surg 45:91, 1959.

In 20 cases arteriovenous fistulae were identified by angiography when they were not visible on the conventional plain film. It is probable that some of the previously mentioned "unilateral" cases are in reality examples of bilateral arteriovenous fistulae which remained unproved because angiography was not employed. Furthermore, a number of unsuspected cases have been found at operation.[9] It is clear that a large arteriovenous fistula does not rule out the presence of other small, inconspicuous fistulae in the same or opposite lung.

Signs and Symptoms

Clinical symptomatology generally becomes manifest in the third decade of life but may occur at an earlier age. In the 140 patients whose records were reviewed by Stringer et al.,[3] 25 to 30 per cent had symptoms from early childhood. Cyanosis is often the first sign to appear, followed by digital clubbing. Both the cyanosis and the clubbing reflect the accompanying arterial oxygen unsaturation. Epistaxis, hematuria, hematemesis or bleeding lips are often the presenting complaints in patients with accompanying telangiectasia. In each instance the size of the lesion determines the severity and, in turn, the age of symptomatic onset. Weakness, dizziness, numbness, faintness, diplopia, thick speech and chest pain probably reflect the associated anoxia and polycythemia.[14]

A murmur is commonly heard over the fistula. It is usually continuous, with maximal intensity in late systole and early diastole. The murmur is generally loudest on deep inspiration and barely audible on subsequent ex-

piration; however, these findings are variable. Sometimes the bruit is audible only over the precordium; in other instances no murmur can be heard at all.[16] One patient had a purely diastolic bruit of increased intensity on deep inspiration.[6]

Blood Volume

Blood volumes have ranged from normal to extremely high values (4,800 to 12,900 cc). Hematocrit levels have been reported from 40 to 84 per cent. The usual hematocrit value is between 60 and 75 per cent.[6]

Physiologic Data

Cardiac Catheterization Studies

By using cardiac catheterization techniques, pressures, oxygen content and saturation, cardiac output and degree of shunt may be calculated and the lesion may be demonstrated by angiography.

Although pulmonary hypertension might be anticipated, it is usually not found with pulmonary arteriovenous fistula. Cardiac catheterization reveals essentially normal pressures in the chambers of the right side of the heart and its tributaries. Systemic blood pressures and pulmonary artery pressures are also normal.[6,16]

Arterial oxygen saturation ranges from 50 to 90 per cent.[3,6] In those patients studied postoperatively in whom a good result was obtained the arterial oxygen saturations returned to normal levels. Preoperatively, breathing 100 per cent oxygen for as long as one-half hour did not correct the unsaturation.[16]

Pathophysiology

The physiologic abnormalities are caused by the shunting of blood from the pulmonary artery to the pulmonary veins (right-to-left shunt).[17,18,19] These changes are similar to those encountered in an area of atelectasis which is in effect a pulmonary arteriovenous shunt, since blood passes through the lungs for gaseous exchange. Arterial oxygen unsaturation and ultimate cyanosis ensue.

Polycythemia

Hypoxemia stimulates erythropoiesis and ultimate compensatory polycythemia.[20,21,22] The reticulocyte count is frequently elevated and blood volume excesses result from the increased erythropoietic activity. The increase in blood volume is mainly cellular, whereas the plasma volume tends to remain at or near normal levels.[6] However, the chronic hypoxemia does not permanently modify the activity of the erythron. In those patients in whom corrective surgery was performed the hematologic studies returned to normal within several weeks.[3,6,9]

Absence of Cardiac Hypertrophy

The absence of cardiac enlargement was noted by most investigators. In contrast, an increase in heart size as well as cardiac output and blood volume is frequently encountered in patients with peripheral arteriovenous fistulae. The lack of cardiac hypertrophy and the absence of pulmonary hypertension in patients with pulmonary arteriovenous fistulae may be related to the lower pressures normally found in the pulmonary circulation.[6,16]

Differential Diagnosis

Polycythemia

More than half of the reported patients with pulmonary arteriovenous fistulae have evidences of polycythemia.[3,6,19,16] In spite of high hematocrits and red blood cell counts, the white blood count is usually within normal limits. This finding is helpful in differentiating primary polycythemia vera. In addition, oxygen saturation is generally normal in polycythemia vera in contrast to the decreased saturation usually found with pulmonary arteriovenous fistulae associated with secondary polycythemia.

X-ray studies, including angiocardiography, are the most useful diagnostic aids. The continuous murmur heard in patent ductus arteriosus may cause diagnostic confusion, but cardiac catheterization will generally differentiate between these two clinical entities.

Pulmonary Arteriosclerosis

Primary pulmonary arteriosclerosis may also be confused with pulmonary arteriovenous fistulae. The most prominent manifestation in these subjects is dyspnea which may be accompanied by cough, dizziness, syncope, chest pain and hemoptysis. In addition, repeated episodes of atelectasis or infarction often occur. The latter findings are especially apt to be confused with the dense shadows of pulmonary arteriovenous fistulae. In primary pulmonary hypertension, however, right ventricular hypertrophy is noted on the electrocardiographic tracings, and cardiac catheterization reveals pulmonary hypertension (in contrast to the normal pulmonary artery pressures found in patients with pulmonary arteriovenous fistulae).

Intrathoracic Masses

Tuberculosis, fungus infections, bronchogenic carcinoma, and other intrathoracic mass lesions must also be considered in the differential diagnosis.

Roentgenologic Considerations

The x-ray findings encountered in patients with pulmonary arteriovenous fistulae depend primarily upon the size of the arteriovenous shunt. The anatomic location is also important since other nearby densities may obscure the smaller vascular lesions. Most fistulae occur in the lower lobes. Not infrequently two or more lesions are present.[3,9]

Pulsation of the tumors may be seen fluoroscopically, and variations in size may be observed coincident with changes in intrathoracic pressure. The fistulae tend to become smaller with Valsalva maneuver (deep inspiration followed by forced expiration against the closed glottis), whereas Mueller's test (deep expiration followed by forced inspiration against the closed glottis) causes an increase in the size of the mass.[10,23] These variations, however, may be subtle and difficult to observe. The presence of transmitted pulsations may also obscure the diagnosis, especially when the tumor is located near the hilum. Lindgren[23] has stressed the importance of careful study of the pulmonary vessels and their relationship to the pulmonary tumor. He believes the latter observations provide the most reliable criteria for making a correct roentgenographic diagnosis. Even small arteriovenous fistulae possess at least two vessels connecting with the hilar vasculature. The pulsation of peripherally located lesions can often be best demonstrated by appropriate kymographic studies.

Pulmonary arteriovenous fistulae usually present roentgenographically as rounded, coin-like lesions located in the lower lobes of the lung.[6,23] Com-

municating afferent and efferent vessels are often visible on the routine chest films, but calcification is not commonly seen.[23] The cardiac silhouette is generally normal. This contrasts with the usual findings in peripheral arteriovenous fistulae and congenital heart disease in which cardiac enlargement is commonly observed.

Special roentgenographic studies offer additional diagnostic aid. Laminography[6,23] may visualize the communicating afferent and efferent vessels more precisely and may also define the location of the lesions more accurately. Angiocardiography usually confirms the vascular nature of the lesions and outlines their connections with the pulmonary artery and veins. This technique may also demonstrate other lesions which are not observed on routine chest films.[3,6,9,23] Special caution should be exercised with the use of angiocardiography since the increase in red cell mass associated with this disease increases the possibility of intravascular thrombosis.[6] Angiocardiography is the most accurate means for making the diagnosis and should be performed before therapy.

Treatment

Since the first pneumonectomy performed for pulmonary arteriovenous fistula in 1940, there has been a trend toward conservatism in the surgical resection of these lesions. Janes[24] in 1941 and 1942 carried out bilateral local excisions. Whittaker[25] in 1944 resected a lobe for this disease, but the patient died postoperatively. Blalock[3] apparently performed the first segmental resection for this disease. Since there are numerous cases of multiple fistulae, and new lesions occur in previously studied patients, it is important to conserve as much functioning lung tissue as possible. The best technique is to isolate the lesion and to resect it in a bloodless field. From the literature a total of 239 cases operated upon resulted in 13 operative deaths.[9] Table 6 shows the results of that series.

TABLE 6

Results of Surgical Treatment*	
Cured	173
Improved	19
Unchanged	2
Operative death	13
No information	32
Total	239

*From Bosher et al., Surg 45:91, 1959.

The indication for surgical therapy is clear in cases with increasing cyanosis, hemoptysis or alarming nervous symptoms. Patients with minimal symptoms run the risk of rupture,[22,26,27] cerebral embolism,[23] and cerebral abcess.[28,29,30] Intervention in these cases will depend on localization, the number of fistulae and the age of the patient. Delaying resection for any but the most minimal of cases seems less advisable in these days of better surgical and anesthetic techniques.

Summary

Pulmonary arteriovenous fistula is an abnormal communication between the pulmonary artery and vein, resulting in a right-to-left shunt. The patient presents with cyanosis, clubbing, dyspnea, and variable neurologic complaints.

Unsaturation of arterial oxygen and polycythemia are characteristic. Diagnosis is clarified by plain chest films, electrocardiogram, and cardiac catheterization with angiocardiography. Treatment is appropriate surgical resection, if possible.

Rietti-Greppi-Micheli Syndrome

This form of hemolytic icterus with decreased red cell fragility belongs in the category of Mediterranean hemolytic syndromes of moderate degree. It is a heredofamilial constitutional disorder that has been observed most frequently in Italians but also in other residents of the nothern Mediterranean coast. Scattered cases, occurring perhaps through heredity and migration, have been reported in various parts of the world.

Erythrocytes are elliptoid, exhibit poikilocytosis, and show increased osmotic resistance to hemolysis and decreased red cell fragility. The intense erythrocytic disintegration is accompanied by signs of increased mechanical fragility. According to Marmont and Bianci, pathologically increased mechanical fragility occurs only in iron-deficient anemias.

The pathologic process varies from a barely perceptible abnormality of the red blood cells to a severe degree of anemia, icterus, and splenomegaly. It resembles or at least has many analogous features of Cooley's anemia; however, variations in the clinical pattern and characteristics make it difficult to classify these cases.

The pathogenesis of the syndrome is speculative. A congenital error of iron metabolism is suspected, involving perhaps faulty stromatohemoglobin bindings. This deficiency is sometimes described as metabolic dyserythropoesis. Although the course is benign, therapy is difficult. As a rule these patients are iron resistant, even to iron given by the intravenous route.

IT'S THE LAW

Insured Denied Recovery for Loss of Foot

An insured individual, whose foot was amputated as the result of injury sustained in an accident, was not entitled to recover the benefits provided in his accident insurance policy for the loss of the foot, because the loss did not occur within 90 days of the accident. The insurance policy stated very clearly that the coverage was limited to cases where the foot was actually amputated within 90 days of the accident.

Finally...a salicylate superior to aspirin?

Not at all, Doctor...but

magan®

(magnesium salicylate, W-T)

should be considered for your arthritic and rheumatic patients who cannot tolerate aspirin.

Surveys * made in 1966 and 1967 among private practice physicians showed an incidence of intolerance to aspirin ranging from 3-85%. The majority of physicians surveyed reported an intolerance in 10-30% of their patients.

How does this compare with your experience?

*by two independent national research organizations

10-30

Don't use Magan on all your patients–

consider Magan for those patients who cannot take aspirin because of gastric discomfort

Private Practice Physicians tried Magan on almost 700 patients whom they judged intolerant to aspirin and other salicylates.

The majority of these patients could take Magan and obtain the benefit of salicylate therapy.

magan® **an alternate salicylate**

(magnesium salicylate, W-T)

May be tolerated by some persons intolerant to aspirin by reason of gastrointestinal irritation.

Magan is a new salicylate product from Warren-Teed.

A single chemical entity . . . no coating, no buffering, sodium free and non-acetylated.

Composition: Each orange colored tablet contains 5 grains (approx. 325 mg) of magnesium salicylate.
Dosage: 1 or 2 tablets every 4 hours with a full glass of water.

Abstracts, Briefs and Commentaries

A FIVE-YEAR HISTORY OF THE MINNESOTA RESIDENTIAL TREATMENT CENTER

The Minnesota Residential Treatment facility is a service arm of the Minnesota Department of Public Welfare which provides psychiatric treatment services for sixty-four mentally ill children. Since July of 1967 the admission policy has been strictly limited to the acceptance of children under twelve years of age. Prior to this date (and this will be reflected in the statistics which will follow) adolescents were accepted at the Treatment Center. Admissions are processed through the appropriate county welfare departments. Initial diagnosis and evaluation studies to determine the needs for residential treatment are carried out by community mental health centers, child psychiatric centers, or by child psychiatrists in private practice. If a child is accepted for treatment, the welfare department of his county pays ten percent of the actual cost of his care and the parents pay the rest, according to their ability, as determined by the county welfare department (in most cases a token amount or nothing at all).

There have been a total of 91 admissions to the facility for the period of June 1963 through December 1967. The ratio of boys to girls admitted to the facility has been approximately two to one, with 59 boys admitted and 32 girls. Other centers report a higher ratio of boys to girls of three to one and four to one. The youngest child admitted to the facility during this time was a five-year, one-month-old boy; the oldest youngster at the time of admission was an adolescent male seventeen years of age. It should be noted that this boy was a member of the first group of youngsters admitted to the facility and remained at the Center for only two months. The average age on admission was twelve years, nine-and-a-half months, and the typical duration of residential care was two years, two and one-third months.

Behavior which comes directly under the scrutiny of the community, such as truancy, social maladjustments, stealing, running away, fighting and temper outbursts, and suicidal attempts, was clearly associated with a significant number of admissions to the center.

A total of 58 children were returned home, eleven to foster homes and eight to other placements such as group living facilities. Therefore 77 children were returned to a community setting, and only 14 required institutional

care. The inescapable conclusion is that the Center has served an important treatment role in terms of resolving the serious psychopathology of these children and in facilitating their eventual return to the community.

There are still voices which can be heard saying that there is no need for residential care and that all children's problems can and should be dealt with in the community. One certainly cannot quarrel with this as an ideal point of view; but unfortunately neither the community nor society in general has achieved such a degree of sophistication and understanding that it is in a position to care for those children who eventually find their way to a residential treatment center. It is evident that when this stage is reached, the family, the school, and the community have literally excluded the child as unacceptable. It is the responsibility of the institution to insist, however, that all these areas continue to be involved in the ongoing care and treatment of the child and to work diligently toward providing a suitable environment for his return to the community.

The residential treatment of children is only now beginning to attract the attention and interest of a society increasingly concerned about the emotional health of its children. We expect that the Minnesota Residential Treatment Center will be in the forefront both in terms of experience and treatment of the emotionally disturbed child in residence.

Minneapolis, Minnesota

EMOTIONS

The limbic area of the brain is the emotional portion where the basic feelings of anger, fear, pleasure, sadness, joy, sociability and sexuality arise. It is known that some people suffer from impulsive sporadic attacks of uncontrollable rage which might lead to homicidal activity.

In the animal the limbic brain has been extensively explored and experiments have shown that electrode stimulation can stop a bull in mid charge or cause a cat to park on a button which delivers constant gratifying shocks to limbic regions. In this manner the electrodes locate troublesome neural tissue which can then be carefully removed.

In the epileptic it is thought that there might be seizure areas in the lower half of the limbic rings, and it is speculated that individuals prone to periodic violence could be victims of focal brain damage resulting from years of bruising emotional trauma.

It has been further suggested that there may be a critical time when the brain learns social behavior.

Carl O. Rice, M.D.

Emotional Brain, Patricia McBroom, Sci News, 94:91, 1968.

ANGIOLOGY

Leg claudication distance can be accurately measured by treadmill. One hundred and fifty-five patients after recording their claimed claudication distance had walking distance measured repetitively on a slow treadmill. The distance was measured as "relative claudication distance" (i.e., when pain begins) and the "absolute claudication distance" (i.e., pain forces patient

to stop).

There was no correlation between the subjective claudication distance and the measured relative or absolute claudication distance.

Claudication distance is affected by motivation, speed and incline of walking, drugs (including placebos) and training.

It was concluded that subjective claudication distance is not a quantitative measure that accurately indicates the stage of vascular disease of the legs.

Jerome T. Grismer, M.D.
Minneapolis, Minnesota

MEDICAL RESEARCH GROUP DEVELOPS ELECTRONIC PROGRAM FOR CONTROL OF TUBERCULOSIS AND OTHER CHRONIC DISEASES

The Medical College of Georgia and the National Cash Register Company together have developed a computerized system for monitoring and analyzing the incidence of tuberculosis and other communicable diseases within a given state or smaller community. The system is the product of two man-years of programming effort.

Under a manual system the scheduling of tests and examinations is ordinarily a tedious operation requiring the attention of a medically competent individual, usually a doctor or a nurse. A TB nurse may spend 20 percent of her time reviewing records.

Under this electronic system the computer can review and update 500 patient records—including the preparation of schedules and the writing of the appointment letters and reports on the 500 patients—all within 12 minutes. The system frees the doctor or nurse for more demanding medical functions. Furthermore, the computer applies a rigid set of criteria to produce consistent results under all conditions.

Editor's Note: Computerized medicine is, for the moment confusing, but it's on the way.

RESECTION OF DESCENDING THORACIC ANEURYSMS WITHOUT LEFT HEART BYPASS

Resections of aneurysms of the descending aorta require preliminary interruption of flow by cross-lamping. Ischemic injury to the spinal cord, kidneys, distal organs and acute left heart failure result if flow is not established. Various techniques (left atrial-femoral bypass, femoral vein-femoral artery bypass, or external shunts) have had problems of flow, heart failure, clotting or excessive bleeding from heparinization.

Two types of external shunts (7.5 mm. cannulas and three-eighths inch tubing; 9 mm. cannulas and one-half inch tubing) are placed into the proximal and distal aorta. No heparin is given. This procedure is especially suitable in acute traumatic aorta rupture and false aneurysms. Eleven patients were successfully operated and aneurysms removed without complications.

IRRADIATION TREATMENT FOR PEPTIC ULCER

X-ray irradiation of the stomach in the treatment of peptic ulcer was first suggested in 1909, and by 1935 over 200 papers had been published on this treatment. Careful studies on thousands of patients have established that irradiation reduced the recurrence rate to one fifth and hastened healing. Nevertheless, this use of irradiation is not generally known and has not been widely adopted. Many prefer surgery despite its risks and the dumping syndrome it often produces.

The technique of irradiation is simple: the stomach is outlined with barium and the skin marked during fluoroscopy. An anterior and posterior field is centered over the upper two thirds of the stomach (where the acid-secreting cells are). An irradiation dose of 2000 r is given through each port in six to eight treatments. In most institutions the 250-kv. apparatus is used.

Results are reported in 121 patients with complicated peptic ulcer, 79 of whom have been followed up for over four years, after cobalt 60 teletherapy. The reactions were minimal.

A total of 629 gastric secretion studies were done. In 90 percent of the patients the basal gastric secretion was reduced more than 50 percent in the first six months, though hyperacidity usually recurred after six months to one year. In 87 cases the ulcer did not recur; in 13 there was a questionable recurrence and in 21 a definite recurrence.

Cobalt 60 teletherapy is a very useful method of treating peptic ulcer, especially in cases where cardiac lesions, hypertension or other complications contraindicate surgery.

THE PARTIALLY SEVERED ARTERY

The incompletely severed artery, unable to retract or constrict, may result in exsanguination, recurrent hemorrhage, arteriovenous fistula or false aneurysm. Fifty-seven patients, selected because of injuries to major arteries of head or extremities, presented with clinical shock (23%), large hematomas that may pulsate (65%), diminished pulses (30% of those recorded) and bruits (53%). Peripheral arteriography demonstrated abnormalities of extravasation, occlusion, arterial defects, arteriovenous fistula or false aneurysm.

Emphasized is the presence of normal or diminished pulses despite partial severance.

Surgical exploration and repair is possible in most patients, i.e., 50 of the 57 patients presented.

In Memoriam

For death betimes is comfort, not dismay,
And who can rightly die needs no delay.

—Petrarch

CLAUDE F. DIXON, M.D.

Dr. Claude F. Dixon, 75, retired Mayo Clinic surgeon, died September 11. He specialized in abdominal surgery and joined the Mayo staff in 1929. After a 29-year career, Dr. Dixon retired in 1957.

He was a native of Piedmont, Kansas, and received his medical degree from the University of Kansas. He attended the Mayor Graduate School in Rochester and was first assistant for two years to the late Dr. Charles Mayo before joining the clinic staff.

Dr. Dixon was a member of the Zumbro Valley Medical Society and the American Medical Association and was a Life Member of the Minnesota State Medical Association. He is survived by his wife and a daughter.

JOSEPH A. POIRIER, M.D.

Dr. Joseph A. Poirier, 88, retired Forest Lake surgeon, died October 9. He was born in Appleton and graduated from Hamline Medical College in 1903.

He started practicing in Forest Lake in 1903 and practiced there until his retirement in 1954.

Dr. Poirier was a member of the Washington County Medical Society and the American Medical Association; was a 50 Club and Life Member of the Minnesota State Medical Association; and served as Forest Lake health officer.

He is survived by his daughter and a son.

WILLIAM D. CLEAVES, M.D.

Dr. William D. Cleaves, 52, Sauk Centre physician, died October 21, of injuries sustained in an automobile accident. He was a graduate of the college of St. Thomas, St. Paul, and of the University of Minnesota Medical School. He had practiced in Sauk Centre from 1946 until the time of his death.

He was a member of the Stearns-Benton County Medical Society, the American Medical Association and the Minnesota State Medical Association.

Dr. Cleaves is survived by his wife, one daughter and two sons.

JOHN A. LEPAK, M.D.

Dr. John A. Lepak, 81, St. Paul physician, died September 28. Born in Gnesen, Minnesota, Dr. Lepak had lived and practiced medicine in St. Paul for fifty years.

He was on the medical staffs of Ancker, St. Luke's, St. Joseph and Charles T. Miller hospitals and held memberships in the Ramsey County Medical Society, St. Paul Society of Internal Medicine, Minnesota Pathological Society, Minnesota Academy of Sciences, Minnesota Academy of Medicine, American Medical Association, American Society of Geriatrics, American Society of Endocrinology and a life fellowship in the American College of Physicians. He was a life and 50 Club Member of the Minnesota State Medical Association.

He is survived by his wife and three sons. Dr. Lepak has two brothers practicing medicine in Duluth, another brother practicing medicine in Oak Park, Illinois and a fourth brother practicing in Oak Lawn, Illinois.

Knee-deep

in osteoarthritic pain

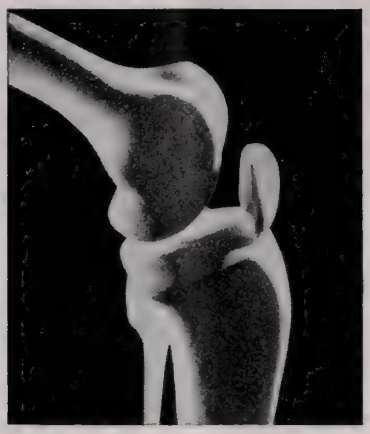
If aspirin doesn't help, move in with Tandearil.

The trial period is brief: 1 week. Try one tablet q.i.d. at first. Tandearil usually starts working within 3 to 4 days. When response occurs, as little as 1 or 2 tablets daily may hold back pain and stiffness, and increase joint motion.

On the next page is a summary of adverse reactions, contraindications, warning and precautions.

Tandearil.
It can help get his mind off his knee.

Please review full Prescribing Information carefully before prescribing.



For osteoarthritic knees, spines, shoulders, hips, etc.:

Tandearil®
oxyphenbutazone

Tandearil, oxyphenbutazone:
For brief summary see next page.

Geigy

TA-6006

Tandearil®
oxyphenbutazone

Contraindications: Edema; danger of cardiac decompensation; history or symptoms of peptic ulcer; renal, hepatic or cardiac damage; history of drug allergy; history of blood dyscrasia. The drug should not be given when the patient is senile or when other potent drugs are given concurrently.

Warning: This drug is an analog of phenylbutazone; sensitive patients may be cross-reactive. If coumarin-type anticoagulants are given simultaneously, watch for excessive increase in prothrombin time. Instances of severe bleeding have occurred. Persistent or severe dyspepsia may indicate peptic ulcer; perform upper gastrointestinal x-ray diagnostic tests if drug is continued. Pyrazole compounds may potentiate the pharmacologic action of sulfonylurea, sulfonamide-type agents and insulin. Carefully observe patients receiving such therapy. Use with caution in the first trimester of pregnancy, and in patients with thyroid disease.

Precautions: Before prescribing, carefully select patients, avoiding those responsive to routine measures as well as contraindicated patients. Obtain a detailed history and a complete physical and laboratory examination, including a blood count. The patients should not exceed recommended dosage, should be closely supervised and should be warned to discontinue the drug and report immediately if fever, sore throat, or mouth lesions (symptoms of blood dyscrasia), sudden weight gain (water retention), skin reactions, black or tarry stools or other evidence of intestinal hemorrhage occur. Make complete blood counts at weekly intervals during early therapy and at 2-week intervals thereafter. Discontinue the drug immediately and institute countermeasures if the white count changes significantly, granulocytes decrease, or immature forms appear. Use greater care in the elderly and in hypertensives.

Adverse Reactions: The more common are nausea and edema. Swelling of the ankles or face may be minimized by withholding dietary salt, reduction in dosage or use of diuretics. In elderly patients and in those with hypertension, the drug should be discontinued with the appearance of edema. The drug has been associated with peptic ulcer and may reactivate a latent peptic ulcer. The patient should be instructed to take doses immediately after meals or with milk to minimize gastric upset. Drug rash occasionally occurs. If it does, promptly discontinue the drug. Agranulocytosis, exfoliative dermatitis, Stevens-Johnson syndrome, Lyell's syndrome (toxic necrotizing epidermolysis), or a generalized allergic reaction similar to a serum sickness syndrome may occur and require permanent withdrawal of medication. Agranulocytosis can occur suddenly in spite of regular, repeated normal white counts. Stomatitis, salivary gland enlargement, vomiting, vertigo and languor may occur. Leukemia and leukemoid reactions have been reported. While not definitely attributable to the drug, a causal relationship cannot be excluded. Thrombocytopenic purpura and aplastic anemia may occur. Confusional states, agitation, headache, blurred vision, optic neuritis and transient hearing loss have been reported, as have hyperglycemia, hepatitis, jaundice, hypersensitivity angiitis, pericarditis and several cases of anuria and hematuria. With long-term use, reversible thyroid hyperplasia may occur infrequently. Moderate lowering of the red cell count due to hemodilution may occur.

Dosage in Osteoarthritis: Initial: 3 to 6 tablets daily in divided doses. Usually unnecessary to exceed 4 tablets daily. A trial period of one week is considered adequate to determine the therapeutic effect of the drug. Maintenance: Effective level often achieved with 1 or 2 tablets daily, should not exceed 4 tablets daily.

In selecting appropriate dosage in any specific case, consideration should be given to the patient's weight, general health, age and any other factors influencing drug response.

Availability: Tan, round, sugar-coated tablets of 100 mg. in bottles of 100 and 1000.

The Physician's Workshop

Pulmonary Function Tests*

Their Laboratory Value

UNTIL RECENTLY respiratory physiology has been the concern of a small number of men in large teaching centers; however, technical refinements and commercialization of instruments have now made pulmonary testing available to smaller centers. The clinician can develop a reasonable approximation of pulmonary function with physical examination, chest x-ray and perhaps fluoroscopy if he repeatedly compares his findings to those of the physiology laboratory. However, good correlation occurs only if the pathophysiologic state is well developed. The laboratory appears then to be the most efficient way of discovering the early or mild case and is the most exact way of evaluating the already well developed pathophysiologic state.

Clinical Signs

A well known modern textbook[5] of pulmonary diseases states: "The patient's response to exercise either walking on level ground or climbing stairs is a rough but reliable index of cardiopulmonary function." Many pulmonary physicians and surgeons agree with the statement to the extent that they feel they can evaluate pulmonary function on this basis without resorting to laboratory testing.

Dyspnea

A recent important study[12] showed that the absence of dyspnea on ascending a flight of stairs *by no means* implied the absence of pulmonary insufficiency (Tables 1, 2, 3). Pulmonary testing is seen to be the most reliable method of discerning the presence or absence of pulmonary disease and of assessing functional status.

Dyspnea, though variously described, is generally considered to be a subjective sensation of need for increased ventilation.[2] The primary function of the lung is to oxygenate and to remove waste products.[2,3] The etiologic factors which can interfere with this primary function are many (Table 4), and clinical separation is often difficult. Function testing using the battery of spirometry, N_2 washout and arterial gas studies, however, will often point to the correct diagnosis.

Cyanosis

The presence of cyanosis may lead the physician to suspect inadequate ventilation. The detection of cyanosis, however, is notoriously difficult; in fact severe pulmonary insufficiency may exist without cyanosis, while in polycy-

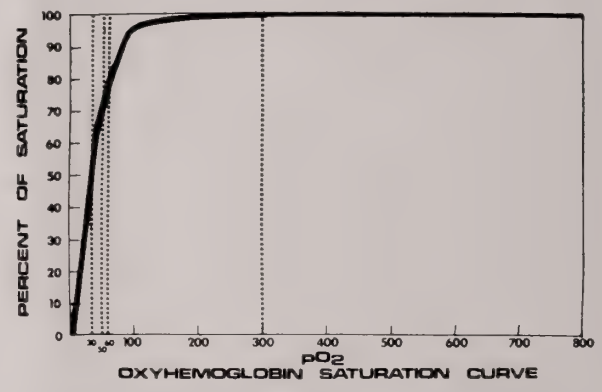
themia severe cyanosis may occur without pulmonary insufficiency.[3]

Laboratory

Arterial blood gas studies are not essential when cyanosis is obvious; but when doubtful, arterial puncture is certainly warranted.[8]

Oxygen Saturation Determination

Oxygen saturation determination is also difficult and at best does not compare in sensitivity with arterial oxygen tension as an indicator of hypoxia.[15] The reason for this lack of sensitivity is the unique shape of the curve of oxyhemoglobin dissociation (Figure).



Oxygen Tension

A low PO_2 in patients with cardiopulmonary disease is likely due to one of the following:

1. If it is combined with an elevated carbon dioxide tension, hypoventilation is the cause.
2. In situations where uneven ventilation perfusion ratios occur in different areas of the lungs, the resultant venous admixture causes the hypoxia. The carbon dioxide tension may be low, normal, or elevated depending on the ability of the lungs to compensate.
3. Venous to arterial shunts are recognized by having the patient breathe 100% oxygen. If at this time the carbon dioxide tension exceeds 550 mm. Hg any significant anatomic shunt can be excluded.[18]
4. In diffusion abnormalities there is usually a drop in the carbon dioxide tension on exercise. However, a definite diagnosis of diffusion abnormality requires a special test called a diffusing capacity.

Carbon Dioxide Tension

Respiratory failure is generally diagnosed when the carbon dioxide tension is greater than 55 mm. Hg and the oxygen tension is less than 55.[18] Respiratory acidosis usually accompanies respiratory failure. It may be acute or chronic, compensated or uncompensated. It is not only the carbon dioxide per se, but the actual pH abnormality produced which can be harmful to the patient. Therefore, in order

Figure—Oxyhemoglobin saturation curve extended to conform to a pO_2 800. At physiologic levels (pO_2 100) the pO_2 is a more sensitive indicator of hypoxemia than O_2 saturation. This sensitivity is accentuated by the inhalation of enriched O_2 mixtures, i.e., a change in pO of 200 mm results in a change of only 3 percentiles of O_2 saturation. Above pO_2 of 300 there is no change in the already fully saturated hemoglobin while pO_2 increases proportionally to the mixture of O_2 inhaled. (Normal individuals achieve a pO_2 of more than 550 while breathing 100% O_2.)

TABLE 3*

Mean Values for Various Ventilatory Data in the Four Groups Paired as to "Yes" or "No" on Shortness of Breath Question

	Yes	No	Yes	No	Yes	No	Yes	No
FEV_1, liters	3.32	3.28	2.10	2.16	2.17	2.68	1.28	1.47
Per cent FEV_1	77.5	75.3	80.6	74.8	53.4	62.0	46.3	53 9
Per cent FVC, predicted	110.3	109.1	68.8	73.4	106.4	116 6	73.3	77.3
Peak flow, liters per minute	548.7	535.3	403.3	394.5	333.7	438.3	186.6	235 2
Percent peak flow, predicted	97.3	93.7	73.9	69.7	60.6	81.2	35.4	45.7

*From Lerner et al. Amer Rev Resp Dis 92:822, 1965 with permission.

to assess respiratory failure or respiratory acidosis, it is almost essential to know the pH, carbon dioxide tension and oxygen tension, and if possible the electrolyte status.[10,4]

Monitoring

Arterial gas studies are required to appraise the status of oxygenation, and these may also be used as a monitoring device in patients who are in respiratory failure.[4,18] Patients with considerable venous admixture, e.g., emphysema associated with pneumonia or severe interstitial fibrosis, often require 45-60% oxygen in inspired air to maintain an oxygen tension between 70-90 mm. Hg, while patients with emphysema and bronchitis alone usually reach these tensions by breathing 30-40% oxygen.[13] Oxygen delivery systems such as nasal and oropharyngeal catheters, nasal prongs, loose masks, and body tents provide only 30-50% oxygen.

Thus, unless monitoring is employed in such cases, an inadequate delivery system may not be recognized. Occasionally the administration of supplemental oxygen decreases the respiratory drive to the point where ventilation is insufficient. Unless the patient is monitored carefully with arterial gas studies, this condition may become apparent only after carbon dioxide narcosis has supervened. In closed systems where the patient is being ventilated through a cuffed endotracheal tube, frequent arterial gas studies are necessary to insure that proper ventilation is being dispensed in order to be able to compensate for the rapid changes in carbon dioxide tension and pH which may occur.

Surgical Risk

Fortunately the chance of a patient developing a respiratory complication during surgery is now less common because of recent refinements in surgical and anesthesia techniques. Filley[8] points out that bad-risk patients with known severe pulmonary disease often do better than patients whose moderately reduced function is unrecognized. The reason for this is that the former patients are watched closely and given intense care while the latter may receive only routine care. It has been recently shown that patients who have abdominal surgery, particularly where large segments of peritoneum have been injured, have remarkably high oxygen requirements. Individuals with only a moderate decrease in ventilatory ability (smokers and bronchitics) who are not usually tested may fail to have their metabolic oxygen needs satisfied in the postoperative state

TABLE 4

Organic Factors Conducive to Dyspnea

I Increased respiratory muscular work.
  1. Central hyperventilation—metabolic acidosis.
  2. Increased ventilatory requirements.
    (a) inadequate O_2 delivery: arterial hypoxemia from high altitude
      anemia
      cardiac failure
    (b) exercise

II Altered physical properties of lung.
  1. Increased elastic work of lung: pneumonia, atelectasis, pleural fluid pneumothorax
  2. Increased elastic work of chest wall: kyphoscoliosis, rheumatoid spondylitis, obesity
  3. Obstruction to air flow: emphysema, bronchitis, asthma, tumors, etc.

III Decreased muscular ability to do work.
  1. Muscular diseases: myasthenia, polio, Guillain-Barre syndrome.
  2. Reduced mechanical advantage of muscle due to:
    (a) marked inspiratory position—emphysema.
    (b) marked expiratory position—obesity.

IV Hypoxia
  1. Hypoxic hypoxia
  2. Anemic hypoxia
  3. Circulatory hypoxia
  4. Histotoxic hypoxia

V Psychogenic

with equally disastrous results.

Postoperative Complications

The majority of postoperative complications, pneumonia and atelectasis, occur in those individuals with obstructive lung disease.[11,13,14,15] Foreknowledge with preoperative pulmonary function tests and postoperative arterial gas studies would help to prevent these complications. Indeed, a pulmonary function screening procedure for all patients who are to undergo anesthesia has been recommended.[14,11] With the advent of the computer there might well be a practical screening procedure for pulmonary function in the future, as are chest x-ray and electrocardiogram at the present time.

Thoracic operations impose great changes on the respiratory system and in addition may superimpose a permanent ventilatory deficit unless the surgery is for correction of a specific mechanical problem. It has been stated by Gaensler that resection for infectious processes is contraindicated in patients with maximum voluntary ventilation of less than 50%, while the Mayo Clinic series suggests 35% as the lower limit.[14] Where cancer surgery is indicated, a pneumonectomy should not be done on any individual with a maximum voluntary ventilation of 55% or less who also does not respond to bronchodilator therapy. A lobectomy is safe on a patient with a maximum voluntary ventilation of greater than 40%.[14]

Disability evaluation is increasingly important—both because of the number of individuals affected with pulmonary disease and because of the demands on the financial resources of the community. It is the physician's job to make an evaluation of ability to work, to give a firm basis for judgment; and the only objective evidence we have thus far on which to make the decision are pulmonary tests.[14] On evaluating obstructive disease, studies of forced vital capacity, oxygen consumption and maximum voluntary ventilation are important criteria of disability, while in restrictive disease arterial blood gases are most necessary. Duplicate testing usually demonstrates malingering.

Conclusion

Although a comprehensive history and a meticulous, skillful examination will frequently uncover the presence or probability of complicating pulmonary disease, patients may be exposed to excessive risk unless baseline pulmonary laboratory studies are done preoperatively. Careful laboratory assessment of the dyspneic or hypoxemic patients is generally necessary to give an informed opinion. Intelligent respiratory therapy cannot be ordered without a knowledge of the arterial blood gas status. Pulmonary disability determination units require the objectivity of physiologic data as a baseline for decision. In short, the physician, the surgeon, and even the bureaucrat require pulmonary function tests for the adequate assessment and intelligent treatment of thoracic problems.

Coronary Care Unit

Model of Medical Organization

WHILE LISTENING to a paper at the Minnesota Society of Internal Medicine on May 18, 1968, presenting the experiences of the Coronary Care Unit at Mount Sinai Hospital in Minneapolis, the manifold implications of this type of unit struck me so forcibly that I decided to write them down. Since I have no personal stake in these units at the moment, I fancy that I am able to perceive the implications with a detached and objective view not possible for those engaged in their planning. Not being involved, I am like a man standing atop a six-story building watching an elephant being washed in the parking lot below. The washers are the hospital administrator, the electrocardiographer, the family physician, the private health insurance provider, the nursing supervisor, the professor, the health care planner, and the patient; each wants to be sure his part of the elephant is clean but cannot view the entire result from his vantage point. This paper is written in the hope that the overview may be useful to the washers. I have a real stake in the outcome of their labors, for there is a great statistical likelihood that I and everyone who reads this paper may one day find ourselves bedded down in a coronary care unit and would appreciate all the effectiveness this new phenomenon is capable of because our lives may depend upon it.

Medical Value

I will ask the reader to accept, as I do, that a coronary care unit can be shown to save lives, compared to whatever care was given prior to the coronary care unit concept. My colleagues tell me that the real value of the unit is prevention of "electrical death," that is, prompt recognition and appropriate treatment of ventricular arrhythmias incompatible with survival. This means that every patient with a proved or suspected myocardial infarction must be monitored for three to seven days, during which time machines and trained personnel must be constantly available to recognize and treat threatening arrhythmias instantly. Once one accepts the premise that a predictable number of lives will be saved, one has no medically defensible position but to insist that the medical profession proceed as rapidly as possible to make this life-saving discipline available to every patient who needs it. There is no other scientific, moral or ethical position one can take regarding this matter.

Economic Implications

When we accept the fact that constructing and staffing coronary care units save "x" lives and cost "y" dollars, we have only to decide what the value of a life is. No small matter! We are told that the price of hospital care is rising alarmingly and rapidly and may soon reach $100 to $150 per day. It is precisely things like coronary care units that cause this increase in hospital care costs. New space must be built or old space renovated to fit new function. Hardware (telemetry equipment) must be purchased. Both nursing and physician staffs must be trained in the use of equipment, interpretation of the alarms it sends, and corrective measures to be applied instantaneously. The cost per monitored bed in a coronary care unit is about seventy-five dollars per day. Can the private insurance sector afford to absorb these costs? If not, will we find it necessary through taxation to underwrite these costs for each other, as a nation? Will the number of

lives saved provide the earning power to support the program? I presume actuarial and statistical methodology exists to answer these questions; but society, given adequate medical leadership, will really decide these questions for us.

Location

If coronary care units are to serve the public best, they must be located in the community hospital rather than in the remote reaches of the metropolitan, university type, referral care center. Acute myocardial infarction happens suddenly and often unexpectedly and must be cared for "in the field." It is a fact in Minnesota that community private hospitals care for the bulk of acute myocardial infarctions, rather than the teaching and research institutions like the University, the Mayo Clinic and the V.A. Hospital, which tend to be at the second echelon level removed by physical and organizational inaccessibility from the acute illness. Even if the second echelon referral centers created such units, we would have to carefully evaluate the possible dangers to the patient caused by separation in distance or in time from optimal early care.

How will the small community hospitals (forty-bed size) solve the problem of coronary care? The answer lies in organization and telemetry. These small hospitals will operate as satellites of a central monitoring station, borrowing medical and nursing skills by sending data and necessary instructions over ordinary telephone wires. They will also need ongoing training programs for doctors, nurses, and technicians, either by sending these people to the central monitor station periodically, or having central monitor hospital staff circulate through the satellites. The situation is analogous to a small company using a time-shared computer: through organization they enjoy computer advantages even though they could not efficiently utilize (or afford) a full-time computer.

Teaching Implications

Inasmuch as physicians are trained at medical school and related hospitals and acute myocardial infarctions are seen at the local community level, it becomes more difficult to teach the care of this disease to physicians in training. It seems likely the universities will have to rotate their trainees (at all professional levels) through the coronary care units of the community hospitals to get this experience. This will perforce involve the medical school more in the medical community, a situation which likely would benefit both parties. I assume the major contributions of the University to the partnership would be research methodology, quality control, and teaching skills, while the major contributions of the community hospital would be facilities, patients, and provision of the training program for nurses, technicians, physicians and allied health professionals. A new kind of professional, the "coronary care nurse," is being born from just that kind of union at present.

People Involved

The coronary care unit offers a new model of teamwork, in which the physician relinquishes some of his leadership role to the nurse. The team consists of a machine at the bedside, a central bank of monitors, a specially trained nurse to form the first human link with the machine, an anesthesiologist, an inhalation therapy technician, the cardiology resident and the director of the coronary care unit. There may be others I haven't named. Each person (or thing) on the team must know his job and integrate his function with that of the other team members to produce the desired result—saving the patient's life. They must train together, scrimmage together, fail together and succeed together. They must be available 24 hours a day, 365 days a year. Any weakness in the team could destroy its functional effectiveness.

Alteration of Traditional Roles

The coronary care model threatens to modify long established doctor-patient, doctor-doctor, and doctor-nurse relationships, and I suspect role modification is going to be most difficult for physicians to accept. When the family doctor admits an acute myocardial infarction now he effects certain surveillance and therapeutic procedures which usually result in recovery. If certain complications ensue he has time to call a consultant, the time-honored method of doctor-doctor teamwork. If the

complication is ventricular fibrillation, and if we assume it will go unrecognized outside of the coronary care unit, the patient may die before consultative help (or any other help) can be obtained.

Acceptance of the philosophy of coronary care units is acceptance of the fact that nobody can predict when the untoward electrical event may occur; therefore all such patients must be monitored. The family doctor must surrender some of the responsibility for care of his patient to "the team" mentioned above. It is doubtful that the team as a consultant can make him a useful member just because it is his patient. More threatening to traditional relationships, the team leader should be the director of the coronary care unit, a full-time cardiologist who may even be a full-time hospital employee. Thus the "hospital" becomes the consultant, and role modification is necessary bilaterally.

Planning Implications

We have already presumed that our threatening new model

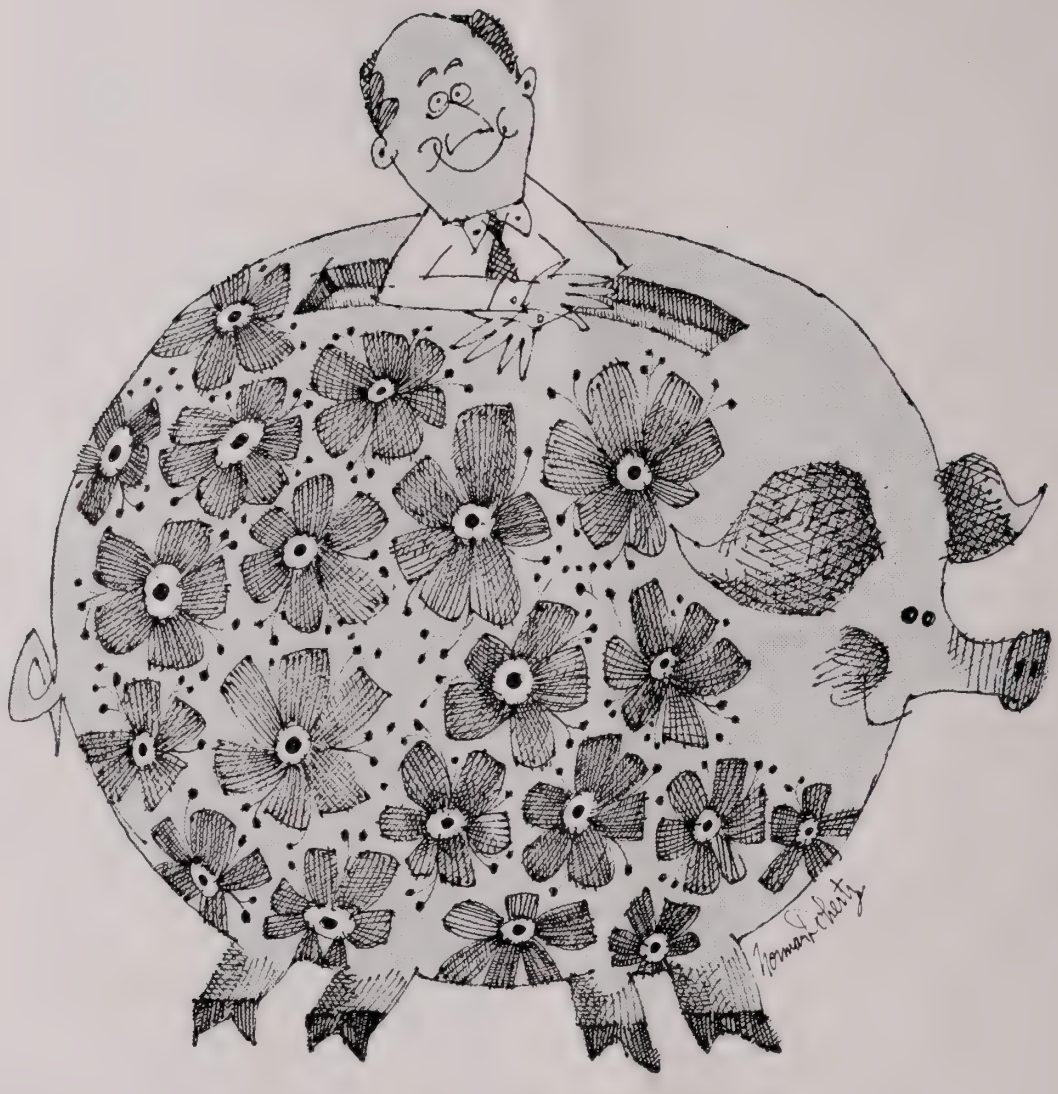
1. has demonstrable and predictable medical value in saving lives,
2. will be very expensive,
3. must be located in the community hospital,
4. should have a teaching liaison with the medical school that is mutually useful,
5. introduces a whole new team approach to a dramatic medical event, involving health professionals at multiple levels, and
6. profoundly alters the traditional doctor-patient and doctor-doctor relationships.

It is obvious that any concept in health care which pervades so many areas requires planning. How many coronary care centers does a state need? Where should they be located relative to population and transportation implications? Who should pay for them and how? Who should train the necessary health professionals to staff them?

To answer these questions the cardiologists are going to have to tell us how many patients with chest pain will present for care next year. Whether every chest pain patient should be monitored in a coronary care unit. For how long? How many beds will be required? Where should they be located? The economists and social planners will have to tell us the best way to finance this care. The community hospitals are going to have to demonstrate that they *can* work together to avoid duplication of facilities and *can* work with the established teaching centers to provide the necessary trained staff.

We seem to be starting off in our usual independent, expensive, unplanned way of having hospitals and their staff compete to see who can build the "biggest and best" coronary care unit. Can we afford this expensive ego food? Can we really learn to work together—family doctors, teachers, hospitals, economists, social planners? Who will lead us?

Summary



It is likely that many people who read these thoughts will have a chest pain some day. When that happens they will want the best care available because their life may be at stake. If accessability to a coronary care unit means the best care available, they will want to be in a coronary care unit.

As physicians we cannot accept any standard which provides less than optimal care, but at present only one or two percent of patients with acute coronary occlusion can enjoy the benefits of an adequate coronary care unit. We must therefore make available what we would like for ourselves to every person everywhere, insofar as it is within our power. The doctrine of one class of medical care for all is desirable as a basic human right. Society demands it and is willing to pay for it. It is our job to organize medical care along new lines every time the need arises. To do this we must subjugate our personal interests, "our own hospital's" interests and "our own medical school's" interests to the interests of our patients, wherever and whoever they may be.

The coronary care unit provides a delightful organizational challenge and, I suspect, is a prototype of many to come. We will have met that challenge if we can ensure that *every* person with chest pain receives the care we would choose for ourselves in a similar circumstance; and having met that challenge, we will be better physicians.

William R. Fifer, M.D.
Minneapolis, Minnesota

It is an infamy to die and not be missed.—Carlos Wilcox

The first thing to save for your old age is you!

Everyone dreams of a pleasant retirement. And practical people save for it. But what good are plans and dreams if you aren't around to enjoy them? Be smart and have a complete health checkup every year. 1,400,000 people living today are cured of cancer. And a yearly checkup could save many thousands more. Plan now to have a future. Make an appointment today for your health checkup.

Experience with Cancer of the Stomach and the Colon and Second Look Procedure*

OWEN H. WANGENSTEEN, M.D.
Minneapolis, Minnesota

SOME OF YOU CONTEMPLATING retirement 50 years hence will see many troublesome facets of the current problems of cancer solved. It has been a great privilege to have had the opportunity over many years to participate in the attack upon clinical problems of cancer at the University of Minnesota. I confess, however, to a feeling of real disappointment over our modest accomplishment. The achievement of a 25-percent survival for gastric cancer which I previsioned 20 years ago has not materialized. Yet I feel certain that with more consistent early diagnosis that objective can be achieved and surpassed.

Cancer Detection

Cancer has been one of my keen concerns during my tenure here; yet I recognize that we have all been too long on the wrong side of the cancer woodpile. In March 1948, our Cancer Detection Center came into being after long struggles with the problem in the School and with the Cancer Council of the State Medical Society. It is necessary to cultivate a spirit of patience while trying to persuade others to one's own point of view. Overnight conversion rarely attends such efforts. While still continuing an aggressive approach to late cancers, we began to direct even more attention to finding methods of detecting early cancer. With the cooperation of our colleagues in the Medical School and the State Medical Society we were provided a good opportunity to search for methods of discovering malignant tumors while they were still asymptomatic. A number of my colleagues over the years have contributed importantly to this effort, including Doctors David State, George Moore, Claude Hitchcock, Brannon Hubbard, Albert Sullivan, Donald Shahon, and the present Director of the Cancer Detection Center, Dr. Victor Gilbertsen. The areas in which a telling impact was made were: cancer of the uterine cervix, rectum and breast.

Chemotherapy—A Mixture of Hope and Disappointment

Professor Haddow of England remarked recently that important progress had been made in chemotherapy, especially with two malignancies: chorionepithelioma and Burkitt's lymphoma. To be sure, that is a good beginning; but many people have undoubtedly shed tears of frustration over what seems to be only a modest accomplishment after so much dedicated effort and lavish expenditure.

Alimentary Tract Cancer

My own special concern with cancer relates largely to cancers of the alimentary canal. When I became a member of the Surgical Staff in the middle 20's we had no records of patients with gastric cancer who had survived for more than a year or two after surgery. Total gastrectomy had not been tried, and five-year cures were few indeed in the hands of the best of gastric surgeons.

There are some areas in which there has been little improvement in surgical management of cancer; surgery for cancer of the breast is a case in point. My experience suggests that this is primarily due to the long silent interval during which the cancer is steadily growing without producing symptoms. By the time the patient does come because of symptoms, we are already dealing with a late cancer. We began 20 years ago to gain some information on the length of the silent, asymptomatic interval in mucosal gastric cancers. Paraffin-

*Presented at the Interdepartmental Cancer Seminar, University of Minnesota, June, 1967.

fixed pathological sections of the resected stomach in six such instances indicated that, unlike the optimistic report of the frozen section at operation, we had left residual tumor behind. We did not then have the courage to reoperate upon the patient shortly thereafter. However, we did have the opportunity to assess the length of time intervening until symptoms returned from continued or regrowth of the cancer. The time interval was approximately two years. The experience indicated how long the latent period conventionally is before the cancer produces symptoms. I think that in dealing with any kind of cancer, this is one of the major problems.

Surgical management of cancer of the lung has come during my tenure. Accomplishments in this field are indeed very modest, and there is a compelling need to devise new techniques for determining the presence of lung cancer earlier in its course. Much good will result from the elimination of one of the important causative agents: tobacco smoking. Some are still skeptical of this; but one piece of interesting supporting evidence is found in Iceland, where most of the country is heated by steam and automobiles are few, but smoking and cancer of the lung are both prevalent.

Incidence of Gastric Cancer

When I started my activities here, gastric cancer took a larger toll than any other cancer in the United States. Since 1940, however, mortality from cancer of the large bowel (colon and rectum) has exceeded that of cancer of the stomach. Today more than 40,000 lives a year are lost from this cause alone in our country.

Reports emanating from many areas of the world suggest definitely that the incidence of and the mortality from gastric cancer have been declining steadily for almost two decades. Contrasting the two-year period of 1952 to 1954 with that of 1962 to 1964 a reduction of more than 35 percent in the mortality of gastric cancer has occurred in white male and female patients in the United States registration area.

Precursors of Gastric Cancer

With regard to cancer of the stomach we have little knowledge of its precursors. Concerning the small adenomatous gastric polyps there is some controversy. The feeling of our own group here, especially of Dr. Lyle Hay who has been an ardent student of the problem, is that when these lesions become 2 cm. or more in diameter they should be regarded as probable cancers; in fact, in our experience, 50 percent of lesions of that size were found to be malignant on histological study (Table 1). Such polyps are the only certain precursors of cancer in the stomach and account for perhaps less than 10 percent of all gastric malignant neoplasms. Konjetzny of Hamburg was a keen proponent of gastritis as an antecedent of gastric cancer; and it has been well established that the atrophic gastritis of pernicious anemia predisposes to gastric cancer.

The incidence of gastric cancer has been declining in Iceland where it was formerly very prevalent. The consumption of smoked meats as a possible cause has been a controversial issue. One of my proteges, Professor Snorre Hallgrimson, said it was his impression from a stay in Minnesota that we ate as much smoked food as they did in Iceland. If smoked food were an important factor, with the prevalence of charcoal broilers in almost every householder's backyard, we should see a great increase in cancer of the stomach, instead of the observed marked decrease. Perhaps the ultimate solution will lie in detecting some other important dietary influence.

Environmental Factors of Gastric Cancer

In January 1967 a very interesting paper by Boyland of the Chester Beatty Cancer Institute

TABLE 1
University of Minnesota Experience with Cancer and Gastric Polyps

	Number	Cancer
Single polyps*		
Polyps less than 2 cm in diameter	81	1 = 1.2%
Polyps greater than 2 cm in diameter	14	6 = 42.8%
Multiple polyps†		
Patients with more than 7 polyps	20	7 = 35%
Patients with more than 50 polyps	6	3 = 50%

*Data abstracted from two papers by Hay
†Patient experience for past twenty years

in London implicated bracken, an uncultivated fern and the curse of farmers in the hill country of southwest England and Wales, as a frequent source of cancer of the alimentary tract of cattle. Evans and Mason produced cancer in the alimentary tracts of mice fed on a diet containing dried bracken. This observation suffices to focus renewed interest on ingested carcinogens as an etiologic agent in cancer genesis. The role of such an environmental influence (smoking) is now well established for cancer of the lung and bladder.

The prevalence of gastric cancer may be diminishing because of less ingestion of carcinogens; the other possibility is that the better diet of 1967 provides more protection against ingestion of carcinogens than did the diet of our predecessors of a generation or more ago. Boyland believes that the carcinogen of bracken may diffuse into water supplies and be ingested by man.

Whereas the atrophic gastritis of megaloblastic anemia, as stated earlier, favors the development of gastric cancer, yet today, with effective treatment of patients with pernicious anemia wth vitamin B_{12}, gastric cancer in this condition seems to be far less frequent than before Minot's discovery.

Case Illustrating the Difficulty in Recognizing Mucosal Gastric Cancer

It is pertinent here to refer to a patient I saw with Dr. Leo Rigler about 20 years ago. The patient had come from another hospital complaining of abdominal pain and was told that he had a defect in the pyloric end of the stomach which, on X-ray examination here, was not apparent. My chief responsibility as a gastric consultant over the years in this hospital has been to ask the simple question, "Has your stomach been pumped?" It is astonishing how often this simple procedure is neglected. On aspiration and histamine stimulation, this patient had 8 mEq. of free hydrochloric acid. Because of pain and the low acid value he was again re-evaluated radiologically, but no lesion was found. However, on gastroscopy a lesion the size of one's palm was described by Dr. Ylvisaker on the lesser curvature in the upper gastric fundus. Thereupon Dr. Rigler, who is certainly one of the finest students of gastric roentgenology, carried out a third study and felt there might be something on the lesser curvature. I did not see or feel a lesion at the time of surgery. Mindful of Dr. Ylvisaker's gastroscopic observation I excised all but five to 10 percent of the stomach. One lymph node was involved with malignancy. The patient, a prominent jurist in the area, continues well and active. He owes his life, therefore, to the evacuation of his gastric contents which indicated the necessity for further study. Abdominal pain and achlorhydria point an accusing finger at gastric cancer.

Japanese Clinicians and Gastric Cancer

Japanese radiologists recognize gastric mucosal lesions by the simple expedient of putting 200 ml. of air into the stomach early in the examination. The air separates very nicely from the opaque medium. The examination is performed in bright light. The examiners rotate patients from side to side repeatedly during the fluoroscopic examination and take pictures in various positions. I saw several small lesions identified in this manner. I was at first a bit skeptical concerning the alleged malignancy of such lesions. However, on returning and submitting the beautiful pictures in Professor Kuru's book on gastric malignancy to my pathology colleagues, Drs. Paul Lober and Robert Hebbel, who reaffirmed the validity of the claims of the Japanese pathologists, I am quite prepared to admit that these mucosal lesions detected by Japanese radiologists are bona-fide cancers. Whether the Japanese use X-ray media different from ours I do not know. Every patient suspected of having a gastric lesion in a Japanese clinic is submitted quite routinely to gastroscopy. In a hospital the size of ours there would be perhaps 10 gastroscopists as busily engaged in clinical gastric studies as are the radiologists. Moreover, the gastric camera is also used quite routinely in such assessments.

Japanese clinicians do less well, however, with esophageal cancer. In an informal conference during the session of the 9th International Cancer Conference held in Tokyo in October 1966, Professor Komei Nakayama said that of 3,000 patients operated upon for esophageal cancer by him and his associates,

in only four was cancer limited to the mucosal surface.

University of Minnesota Medical Center Experience with Gastric Cancer

To sum up our experience with gastric cancer: we have had some 1,756 cases from the beginning of our study in 1936 until 1958, comprising the total number seen in the clinics or wards of the University Hospitals. Of that number, we operated on 89 percent and did resections in 80 percent of the patients; but our overall success was very modest. I had previously expressed the hope that before I put my scalpel down we might actually have five-year survivals on the order of 25 percent; but the best we have been able to accomplish is a 17-percent five-year survival, though many of these patients survive for 20 years and more. However, of the patients who came in with local lesions, the five-year survival rate adjusted for age is 55 percent; and in some small series in which the lymph nodes were negative, we had as many as 70-percent five-year survivals (Table 2).

Inasmuch as Japanese clinicians frequently recognize gastric cancer limited to the mucosa or submucosa, their cure rates are considerably better than ours. In fact, reports from Japan suggest that of patients currently undergoing resection of the stomach for gastric cancer, 20 to 25 percent show involvement only of mucosa and submucosa. Japanese surgeons report a survival rate of nearly 100 percent in such cancers. Only by following their diagnostic precepts can we begin to emulate their success with gastric cancer.

The Second-Look Procedure for Gastric Cancer

"Second-look" surgery for cancer of the stomach has been less successful than second-look surgery of the colon. Of our uncured second-look patients with gastric carcinoma, 19 percent were alive at four years; therefore the procedure in these cases did extend life. Even though the second-look procedure produced only eight percent five-year survivors in patients with residual gastric cancer on the first surgical re-entry, it did succeed in prolonging life, even though it failed to cure. Is this not better than telling the patient there is nothing more to be done for him? (Table 4).

Cancer of the Colon

In the surgical management of cancer of the colon, I have been partial to near or total colectomy for cancers distal to the hepatic flexure in standard risk patients since the middle 40's. I recall a patient in 1955 who had undergone two prior excisions for cancer of the colon in another clinic. Two years after the last procedure his physician sent him here. There was a new extensive lesion in the transverse colon. A total colectomy was done, anastomosing the ileum to the rectum. On being

TABLE 2

University of Minnesota Experience with Second-Look Procedure with Cancer Present on Re-Entry

Site	No. of Patients	Five-Year Conversions
Stomach	38	3 = 8%
Colon	40	7 = 17%
Ovary	11	2 = 22%
Retroperitoneal sarcoma	10	3 = 30%

informed of the extent of colon removed the patient asked why that was not done in the first instance? The same question bears repetition today. My experience has taught me that all patients operated upon for colon cancer, having less than a near or total colectomy, need annual air contrast barium enema studies. Over a two-year period I saw three patients with a new colic cancer, whose initial operation had been done 13 to 18 years before.

In standard-risk patients, near or total colectomy can be done with operative hazards not far out of line with those incurred in segmental or hemicolectomy. I am partial to the closed method of anastomosis and to an anastomosis between the cecum and the rectum. The alternative is ileoproctostomy with excision of no more than one or 2 cm. of the ileum. We have yet to see a patient with near or total colectomy with persistent diarrhea.

Our best series of consecutive cases of colectomy in this hospital was in the two-year interval of 1941 to 1943 when 61 partial colectomies, employing the closed anastomosis, were performed—with only one hospital death*. Penicillin in very small quantities became available for civilian surgery for the first time only in the summer of 1944. The important desideratum in colon surgery is precise technique with complete avoidance of spillage (Table 3).

The Second-Look Procedure for Cancer of the Colon

Japanese surgeons are more alert to the potentially greater hazards of so-called "Dukes' B" lesions in which penetration of the cancer to the surface occurs. The second-look procedure was first undertaken in this clinic for cancer of the colon in 1948. When I first proposed the procedure to a patient who was found to have an extensive cecal cancer with large clusters of grossly positive lymph nodes in the ileocecal mesentery, the patient asked me, "What evidence have you as to the likely value of such a procedure and what experience have you had?" I admitted that I had had no experience but explained the disparity in accomplishment between lymph-node negative and positive cases. She accepted my suggestion and returned six months later for re-exploration. This patient with an aggressive cecal lesion had six looks before the last re-exploration was negative for residual cancer. When I had the privilege then of telling this courageous lady that there was no residual cancer, she shed a tear; whatever her emotions were, she was too brave to weep outright. She died 12 years later in this hospital of a cerebrovascular accident; no evidence of cancer was found post mortem.

The accompanying chart (Table 4) summarizes our experience with the second-look procedure for cancer of a number of intraperitoneal organs. Three of 10 patients with rhabdomyosarcoma (30 percent) were salvaged and converted to a cancer-free status by second-look operations; 22 percent of 11 patients with cancer of the ovaries were salvaged; for the colon the salvage rate was 17 percent, with eight percent for the stomach.

Patients with Cancer Should Be Told

Obviously patients undergoing second-look procedures should be frankly informed of the nature of their illness. A number of years ago I heard Lowell Thomas say on the radio that Babe Ruth (August Herman), the great hero of baseball, had died of cancer, and that he was very fortunate not to have known that he had the disease. My experience tells me, however, that if you fail to tell a patient, you are doing him a gross injustice. Often when I tell a patient that he has a cancer, he will say, "How glad I am you told me because now I can discuss it with my husband (or wife) who does not know that I know that I have cancer." In other words, if you deceive the patient, he will participate in the deception. Leon Tolstoy wrote very interestingly of this situation in the Death of Ivan Ilych, a brief essay that every medical student should read. It concerns a successful Russian lawyer who probably had cecal cancer. The physician, the patient's wife and his daughter participated in the deception by not telling Ivan the true nature of his illness. They obviously were not yet prepared to face the Gethsemane in another's life. Their daily round of responsibilities and pleasures could not be broken. When is sincerity more appreciated than by a sick person who is too weak to fight back? Husbands will say, "Don't tell my

*Surg 14:403, 1943.

wife she has cancer." However, the physician's greatest responsibility is to his patient. Moreover, from long experience I can tell you it is the wisest policy to tell. One must *never,* of course, extinguish hope.

I was interested in the problem presented earlier today. That patient demonstrated the tenacity with which people hold onto life. I have been told by a few friends that if they were discovered to have cancer, nothing should be done about it. It is amazing how such a person's mind changes when he learns that he actually has cancer. It is then *his* problem; before, it was *only* a philosophic matter. Much of my work has been with geriatric aspects of surgery. In resolving the mode of management of a problem in a patient well along in years in the outpatient clinic, my first question usually is, "How old do you want to live to be?" Answers are uniformly the same: "Well, as long as the weather is fair and the company reasonably good, do what you can to keep my poor craft afloat." Life is still dear to most men in the eighth, ninth, or even tenth decade. Even the suggestion that you are sincerely interested in trying to do something, even in desperate situations, is a source of great hope and inspiration to patients.

Finally, I would like to stress the need for surgeons thinking broadly—beyond the borders of their own field when dealing with cancer. Early detection can pay great dividends, of which there is abundant evidence in cases of cancer of the cervix, with a reduction of mortality of 50 percent (United States figures). Approximately 90 percent of patients with early cancer of the breast detected in our Cancer Detection Center were alive five years later, an achievement far superior to that of patients who come to the hospital with the clinical diagnosis of breast cancer. And similarly with early detection of rectal cancer, as the work of our Cancer Detection Center clearly demonstrates.

If we can rival the accomplishment of Japanese clinicians with gastric cancer and Swedish radiologists in the early detection of cancer of the colon, the young surgeon of today emerging from his years of clinical training will have the opportunity to make a more telling and durable impact upon the problem of visceral cancer than have the surgeons of my generation.

This story serves to reaffirm the interdependence of our professional disciplines. A significant advance in one is reflected in many others. A surgical Rip Van Winkle of today looking in on the activities of his surgical colleagues 50 years hence will be heartened by their greater progress in the field of cancer cure.

We have too long been "Prisoners of hope" in dealing with this disease. Until the pursuit of the nature and causes of cancer eliminates some frequent cancers, cancer detection obviously must be our hope and refuge.

For the privilege of retelling this story, I am grateful.

Book Reviews

The proper study of mankind is books.—Aldous Huxley

ANESTHESIA FOR INFANTS AND CHILDREN, by Robert M. Smith, M.D., Anesthesiologist, the Children's Medical Center, Boston, Massachusetts, the C. V. Mosby Company, 1968, Third Edition. 530 pp., 240 illustrations. $17.50.

This third edition of Smith's popular book will contain few surprises for those already familiar with its predecessors. The changes in this edition reflect what has happened in anesthesiology in the past five years. The increasing acceptance of halothane and the enlarging scope of the anesthesiologist's practice outside of the operating room are two examples. But for those unfamiliar with previous editions, those new to the specialty, and even for the many physicians who treat children, the book is highly recommended.

This is first and foremost a very practical book. In it the author describes the problems that are peculiar to pediatric anesthesia and how he and his colleagues have solved them. About one half of the book is devoted to such things as "Anesthesia for Infants Under One Year of Age" (chapter 17; 32 pages) and "Anesthesia for Pediatric Neurosurgery" (chapter 21; 13 pages). These are practical sections with many illustrations and photographs. Midwestern anesthetists will be interested in the enthusiastic advocacy of nonrebreathing techniques, particularly modifications of the Ayre's T-tube, which is not commonly used here.

Dr. Smith knows his subject well and is a most learned and expert physician. However, the success of the book is due at least as much to his power of analysis and exposition, his dry wit and a lucid, simple style, as to his reputation.

Van S. Lawrence, M.D.
Minneapolis, Minnesota

MODERN NUTRITION IN HEALTH AND DISEASE. By Michael G. Wohl and Robert S. Goodhart; Fourth Edition; plus 1240 pp. Lea and Febiger. Philadelphia 1968. $30.00.

This work now in its fourth edition and fifth printing has become a classic textbook in the field of nutrition. There are seventy collaborators. Part I concerns normal nutrition with chapters on body weight, absorption of food, hunger, the usual carbohydrates, proteins, and fats, vitamins, and minerals. Part II is concerned with nutrition in disease. A surprisingly small chapter, less than forty pages, suffices for diabetes mellitus. Part III is an extension of nutrition considering various physiological states such as pregnancy, infancy and geriatrics. A fascinating chapter deals with intoxicating foods, of which there are an extraordinary number sufficient to destroy one's enthusiasm for a ramble in the woods seeking plants, berries, and mushrooms to enhance the daily diet. Most of the chapters are appended with numerous references, many of which deplorably follow the European style, omitting the title. In this country the general opinion is that, next to the names of the authors, the title is the most important part of the article. Modern Nutrition in Health and Disease is recommended as a standard text in the field.

Reuben Berman, M.D.
Minneapolis, Minnesota

MAY YOU LIVE IN HEALTH. By Aaron Friedell, M.D., 69 pages, Minneapolis, Minn.

In Psalms 139:14, David says of himself that he is "fearfully and wonderfully made." So are we all!

Just how fearfully and wonderfully is conveyed by this compact little book wherein Aaron Friedell informs us by text and illustration how precisely and intricately structure and function correlate in the human organism. It is a book for anyone to profit by. For the few of us who have never realized the amazing complexity of man's anatomy and physiology the book is a revelation; for the rest of us a fascinating review.

The figures and diagrams are excellent; they come warm and alive under scrutiny: cells, tissues, organs, systems—each making its own unique contribution in the "pentagon" of optimum health: proper diet, exercise, elimination, breathing, and mental attitude.

Such a book could conceivably be dull; but this one is not. From page one on, the author's clarity of style and sincerity of conviction carry the reader along effortlessly, setting him down at page 69, resolved to eat, breathe, exercise, eliminate, and think *right*. And that, after all, is the main purpose of the book.

Doctors might do well to recommend MAY YOU LIVE IN HEALTH to their patients and to follow its advice themselves.

A Psychological Field Theory of Adolescence

MARSHALL D. SCHECHTER, M.D.*
Oklahoma City, Oklahoma

ADOLESCENCE IS A period of internal destruction of early parental images and a vigorous drive toward replacement by attachment to new objects. The symptoms seen at this time of life—whether a mild mood change or more intense depressions (including suicides), psychotic withdrawals or antisocial activity—can best be understood as a manifestation of problems surrounding the separation and destruction of internalized primary objects and the finding of suitable new ones. Treatment is aimed at fostering the break with these infantile images and aiding the replacement with satisfactory, stable and worthwhile object ties.

This presentation is an attempt to form a theoretical basis for repeatedly observable clinical phenomena during adolescence. As an introduction, I will describe a brief encounter between a child and his mother to illustrate the conflicts to be anticipated during the process of adolescence.

An argument took place between a preadolescent and his mother. As it grew more heated, the boy decided to run away from home. His mother asked how he would eat. He stated that he would take money from his bank. She asked where he would sleep. This he said was none of her business. She wondered about clothes and keeping warm. He said he'd pack a knapsack. Then his mother said that she was sorry that he felt so angry and that she and his father would be very worried. The boy answered that he would write. His mother asked what he would say. His answer, half in jest, was, "Wish you were here!"

Normality of Process

It is my hypothesis that depressions and mood changes in the adolescent are developmentally normal. The alterations that occur are functionally related to the destruction of the primary infantile tie with the parents (the introjects) or internal images with subsequent periods of mourning and/or its psychic partner by denial, elation. In the adolescent, the destruction is slow, continuous and repetitive as well as explosively sudden, discontinuous, and reparative. It is in the normal that we see mainly the *mood* shifts with generally a preponderance of depressiveness (the blue moods). This is especially noted when the partially lost internal object is not replaced immediately by attachment to another suitable, worthy and valued one. It is during these transient episodes of breaking the parental tie (i.e., the destruction of the introject without substitution) that feelings of worthlessness occur. At the same time, anxiety is increased as the sexual and aggressive drives are not secured by attachment to a steady, acceptable non-punitive individual.

Deviations from Normal

It is in the more severe deviations of the normal or in the overtly pathological that either (1) the objects are not given up at all but are kept inviolate by idealization, or (2) the infantile attachment to parents is so completely withdrawn without replacement that it is necessary to regress to pathological self investments, or (3) the energy is directed toward inappropriate, unrewarding and often sadistic objects. In the cases where the inter-

*Professor of Child Psychiatry and Consultant Professor of Pediatrics, The University of Oklahoma Medical Center, Oklahoma City, Oklahoma. Presented at Center for Continuation Study, University of Minnesota, February 8, 1968.

nalized parental images (the introjects) remain fixed and unchangeable, the adolescent has a "Peter Pan" look and behavior. His chronological physical development is often belied by a face that looks much younger and by actions that are more naive and immature. These children often have feelings of emptiness or manifest depressions.

In the cases where the infantile attachments to parents are withdrawn completely without replacement, the regression gives the clinical picture of psychosis or a severely regressive psychosomatic disorder. In the cases where the infantile attachments to parents are *almost* entirely withdrawn, the symptomatology is that of depression which might lead to suicide.

In the cases where there is a substitution of improper objects, antisocial behavior results. Anna Freud[2] stated, "Where adolescence is concerned, it seems easier to describe its pathological manifestations than the normal processes. Nevertheless, there are at least two pronouncements which may prove useful for the concept: (1) that adolescence is by its nature an interruption of peaceful growth, and (2) that the upholding of a steady equilibrium during the adolescent process is in itself abnormal."

Conflict Impulses

Edith Jacobson[3] noted that the adolescent has not only to finally relinquish his sexual and hostile wishes; but even his affectionate ties to his parents must be loosened. This, she says, is the cause of his grief reactions. What makes it even harder is the fact that it involves also a definite and final abandonment of his practical and mental dependency on the parents. Speaking of the "inner loss" of the infantile love objects in the adolescent, Jacobson says, "It is significant that within the margin of normal development, adolescents may pass through transient periods of narcissistic retreat to the point of real 'inner' object loss. What is *decisive* is less the brief duration than the reversibility of such states."

Jacobson compares adolescent mood swings to the beginning of a schizophrenic process and relates them to self-centeredness reflecting the floods of instinctual energies which have been liberated but not yet attached to new individuals. She comments upon Anna Freud's[1] remarks about the ego treating the superego (conscience) as though it were a taboo lover. Jacobson says, "This is certainly correct. But we may go even further in our understanding by considering besides that these defensive attitudes of the ego toward the superego are part of the adolescent's desperate struggle for freedom and for independent individuality, and hence an expression of the ego's rebellious refusal to 'submit' or 'admit' to any authority or influence, be it from *without* or from *within*."

Conflict

I think one can see the adolescent's need to reorient himself to new object relations—a need to withdraw energies and thus modify his early object relations, particularly since there is such a heightening of both the sexual and the aggressive drives. We can see in teenagers a struggle to maintain contact with parents, but a fear of closeness. We can see a struggle over their desire to be independent while hating the parents who do not demonstrate an interest in them even if the interest centers about saying "no" to their desires. We can see a struggle to freely discharge sexual tensions even if only through fantasy, while yet attempting to reinforce repressions as the fantasies come too close to involving unresolved oedipal attachments.

It is my belief that the rapid shifts in the adolescent's "crushes" are necessary escapes from primary love objects. When in love, the teen-ager is manic-elated; when out of love, morose-depressed. During periods between loves, the feelings of inner loss are often so intense that the adolescent notes severe feelings of depersonalization. Since other symptoms of psychotic disorder can occur simultaneously, one needs to view the past emotional life of these patients and the tendency toward reversibility of these affective states before reaching the diagnosis of a schizophrenic reaction.

Pathology

Anna Freud[2] noted, "Further pathological developments of this state of affairs are worth watching. The hostility and aggressiveness, which serve as a defense against object love in the beginning, soon become intolerable to the ego, are felt as threat, and are warded off in

their own right. This may happen by projection; in that case the aggression is ascribed to the parents who, consequently, become the adolescent's main oppressors and persecutors. In the clinical picture this appears first as the adolescent's suspiciousness and, when the projections increase, as paranoid behavior.

Conversely, the full hostility and aggression may be turned away from the object and employed inwardly against the self. In these cases, the adolescents display intense depression, tendencies of self-abasement and self-injury, and develop, or even carry out suicidal wishes."

Parent vs. Child

Just a few words about the parents of the children who have gross difficulty through adolescence. It has been my experience that there is certainly a reawakening of the parent's own adolescent struggles. But besides this, many of these parents are primarily depressive individuals themselves, who find separation from their children as hard as separation from their own parents. They often are immature, dependent people who have identified with their children and bound them with many gratifications in the early years but then later expected them to satisfy some of their own needs. There is frequently an increased awareness of conscious and unconscious parental attitudes by the adolescent, who at times reacts to these negative feelings. Sudden lessening of parental esteem has the effect of speeding the destruction of the internalized infantile parent images, often resulting in a furious outbreak of delinquent behavior or violence.

Clinical Material

Acting Out as a Means of Replacing Destroyed Objects

Laura, the oldest child of a prominent professional man, was referred because at age 18 she was twice illegitimately pregnant within a four-month period. Her parents were especially concerned, as they felt she did not care what happened to herself; but, much to their surprise, the girl agreed to treatment rather willingly. She was very defensive at first in the interview situation. When asked what the difficulty was, she reiterated what her parents had said. She also stated that she did not even care if she became pregnant again just so long as she could once more date the boy who first made her pregnant. I said maybe this could be cleared with her parents if she really wanted it after our talks, but perhaps her boy friend might not be so willing.

She asked if all that we discussed was confidential and, when told it was, her masked facies changed to a bitter sadness. She told how she was overwhelmed with guilt; how her mother did not understand and never would understand her, and how her father was too involved with his own affairs to pay any attention to her.

The first boy she was impregnated by still captured her thoughts. His major value was his sureness and certainty in handling details of life. He seemed interested and listened to her if she had problems with her parents or other boys. It was this protectiveness and concern about her that finally led to the seduction. In later hours there were elaborations on this theme of how she needed someone strong to guide her and again hints as to her parents' failing her at some particular point. The guilt she spoke of was not that her peers would find out but rather how painful this all was to her parents. Finally with much hesitation and depression she spoke of learning at age 14 of her father's infidelity. She was told by her mother in front of her father and asked to choose between them if a divorce should take place. It was at this point that she felt her world crumbling. All the confidence she had placed in her father was shaken. With the confrontation, she felt weak and helpless and very much identified with her father whom the mother was berating and degrading incessantly. From this time on she began looking for objects to replace not only the debased father but also a vitriolic unaccepting maternal object.

"Peter Pan Syndrome"

Bill's parents brought him for treatment because of an episode of petty thievery which to them appeared childishly illogical and senseless. He had stolen some film from a grocery store where he was well known and where he had been caught stealing just six months before. Bill, who was 16, had many other symptoms,

which included severe suicidal depressions, no friends, thumb-sucking, learning problems despite a high I.Q. and a persistent acne that resisted all dermatologic treatment. This boy was about as tall as his father but was round-faced and cherubic in appearance. He was weighted with depression and guilt. Each time he closed his eyes, he would relive the entire episode of the stealing and the events that followed in the sheriff's station and at home. Throughout his treatment he would return to this event as it represented an attempt at breaking away from his parents—especially his mother—and the subsequent punishment for his flight into independence. He was able to recognize that through the years not only was each act of independent activity sabotaged by himself, but his parents also made independence unacceptable. His fantasies, as he sucked his thumb, consisted of constant fulfillment of all his wishes by a non-punitive, all-giving mother.

Analysis was subscribed to by the parents on a conscious level. Despite this, shortly after treatment began, they kept making so many remarks about the cost in time and money that after the second month Bill came in and announced his decision to terminate treatment. It was at this time that I pointed out the unconscious motives of his parents who were attempting for their own needs to keep him infantilized. He could see on this occasion that they said one thing and then reacted oppositely.

Shortly after this, despite many complaints from his parents about his lack of friends, when Bill made two appointments with friends after school, his parents insisted on knowing the details of his contacts and objected violently to his being five minutes late for dinner following a meeting with his friends. Throughout treatment these discrepancies were reported. Each time Bill was able to note his parents' unconscious motivations, he was able to draw further from them and closer to the analyst. At the peak of his revolt, his grades hit the lowest point of his life. It was evident that he could not accept the authority of his own ego ideal to accomplish his own goals of being an "A" student. The mere fact that somebody or something (even inside himself) was telling him to study was enough to make him go in the opposite direction.

During these periods of total rejection of the introjects, he would report weird detached depersonalized sensations even to the point of having difficulties remembering the shift system of his car or the route to get back to his home. During the terminal portions of his treatment, his organization was so secure that during the usual arguments with his parents about any of his activities he would remain silently aloof. His acne cleared with only one exacerbation when he became aware of his parents' shifting their dissatisfactions onto his sister and his momentary flareup of anger with them again for their lack of understanding.

Regression and Depression

I saw Don off and on for a period of nine years, starting at age 14. His major symptoms included enuresis, a persistent fantasy of making love to girls by beating them first, and fear of the hostility of other boys. All through his treatment until he was in his 20s, he maintained excellent relationships with his parents which he kept questioning, as he knew the revolt adolescents were supposed to go through.

On completion of college he returned for treatment because of depression, which came on when he was touring Europe and attempted to form a sexual relationship with a woman there and was unable to have an orgasm.

Subsequent treatment revealed a persistent, unconscious, homosexual attachment to his father that was threatened by his attempted heterosexual attachment. His enuresis, beating fantasies and fear of injury from his peers, plus the inability to become independent, could be seen as a need to submit passively to an omnipotent male. With the emergence of his sexual desires, he was faced with the possibility of giving up his attachment to his father; and the act of intercourse and the analytic treatment were seen as the beginning of the demolishment of his father's introject. The depression was partially solved by his going into business with his father and giving up treatment.

Regression to Psychosomatic Disorder

As part of the treatment of an epileptic adolescent, petit-mal and grand-mal attacks could be precipitated almost at will whenever sub-

jects dealing with the loss of object relations were mentioned. For example, even though he would give his epilepsy as his reason for not getting a job, the mechanisms beneath this were the same as we see in a school phobia. He was afraid of loss of contact with his mother and her possible death when he was away. This resulted in panic, as her loss was equivalent to his own annihilation.

Infantile Ties with Parents

Kathy was 15 when I first saw her. Her major symptoms were depression and obesity. Treatment was recommended but not continued after the diagnostic workup. Eight months later she was again seen—three months pregnant. The depression was still present but there was an air of satisfaction and elation as she told me that her father was going to arrange for her confinement. The next day the gloating was gone, however. Her father had failed her. The depressed reaction was intense. I arranged placement and saw her through the pregnancy and for a year afterward.

Briefly this was the history: She was the only child of parents who were divorced when she was three years old. She was intensely in love with her father at the time of the separation. Whereas the father remarried and had children with his second wife, her mother did not remarry but continued weekly visits with the patient to her father's house to keep up "friendly relations." When together the father seemed interested and concerned; however, he never made any visits to the child or any arrangements to have her with him.

After puberty, her father became very curious as to her relationships with boys. She confided in him, as she felt her mother really wasn't interested. At the first sign of actual sexual involvement, the father made Kathy promise that she would not indulge unless and until he himself initiated her. She loved him a great deal and felt that she probably would really be acceptable if she showed him she was the best "lay" he ever had. Sexual relations began and continued along with other completely casual ones with pickups at bars. There was even some question as to whether her father was the father of her child. No matter how flagrantly he ignored her, she still cherished the fantasy that he was interested and loved her.

During the entire confinement and the year afterward he made no attempt to contact her. Nevertheless, each Christmas and birthday she considered giving him an expensive gift which she could ill afford. Whenever she was confronted with his lack of interest, she became depressed to suicidal proportions. At these times she would try to elicit signs of her mother's interest but always failed.

Her acting out with men became clear; it was not only an attempt to get the father image she fantasied but also hopefully to have her mother demonstrate an interest by insisting she stop her sexual escapades. Her mother's lack of firmness increased her anxiety, as it drove her again and again to try to find satisfaction from imaginary father figures. She begged for an authoritative figure who could control her impulsive sexual activity and her eating. Not only was her father of no help in supporting superego formation; but when Kathy finally decided to diet, her mother for the first time in years began baking and bringing home pastries and ice cream.

In treatment, Kathy focused all of her longing for a consistent object on me, her analyst, and felt good when she was not allowed to act out without criticism from me. Before each turn to me, there characteristically had to be an episode of disappointment with her parents, a depression, an acting out and then finally an accepting of me as a new, more stable object.

She graduated from high school, and her weight continued diminishing. After this she entered college and worked, all in a city quite distant from her mother and her father.

Parental Roles

There are many times when the treatment program of adolescents is interfered with by the problems of their parents. This could be seen in the case of Bill and Kathy, as well as in the case of Shirley who at 17 was referred because of two abortive suicidal attempts. Shirley was a well-developed, attractive but surly-looking girl who could only talk about her potential successes with boys, her potential

successes in an acting career and her potential successes in her academic work. In actuality, boys took her out only because of what they "could get from her;" drama teachers turned her down repeatedly as she would not take directions, and she had failed one semester and was on her way to another failure because of non-attendance in high school.

Besides these shortcomings, Shirley, who was an only child, would engage periodically in violent physical and verbal battles with her mother, Shirley threatening to kill and her mother threatening to call the police, while her father remained passively unconcerned. This was the picture when I was first consulted.

After a short period during which Shirley blamed everybody and everything for her derelictions, she finally decided that to achieve in any sphere would require some action by herself. I was able to show her how inconsistent her parents had been. For instance, when a punishment was given, it almost immediately was rescinded despite Shirley's partial insistence on fulfilling it. Or, despite her mother's conscious desire for Shirley to go to school, she would sanction any excuse to allow her child to remain at home. The more Shirley saw of these tendencies in her parents, the more distant but simultaneously the more depressed she became. Concurrent with mood shifts in treatment, her mother became more openly provocative and seductive, constantly precipitating fights and then offering unusual rewards during the making-up periods. I received many calls from the mother, complaining about how badly things were going with Shirley. But in spite of these complaints, the mother constantly took the blame on herself, saying she knew she deserved this treatment and realized that she should not have done or said something that precipitated the new fight —but she "just couldn't help it."

Finally, when Shirley spoke of her mother's tendency to incite arguments on the flimsiest of excuses, I suggested that perhaps it would be best for her to say that she did not want to fight and to isolate herself in her room. Three hours after this recommendation, which Shirley acted upon, I received the most blistering denunciation from the mother. For the first time, I was accused of trying to take her daughter away from her and she was "not going to allow it." Treatment was interrupted shortly after this because of supposedly sudden and unusual financial problems.

Destruction and Replacement of Parental Images

Janet, the adolescent daughter of a friend, came home one day and announced that she felt depressed. When questioned by her mother, no difficulties could be discovered either in her academic or in her extracurricular affairs. She isolated herself for the rest of the evening until bedtime. When she came to say goodnight to her mother, Janet led the conversation around to marriage—the interpersonal as well as the sexual relationships in it. With much dramatic inflection, she announced it was all very disgusting. She questioned and verbally abused her mother who considered love still beautiful and exciting even at her age. Finally, when her mother despaired of her ever retiring that evening or ever having a happy relationship with a man at any time in the future, Janet announced with glee that she had a date the very next night with the handsomest boy in her class. The depression evident at the beginning of the conversation was over at its end. When her mother commented on it the next day, the rapid shift in mood was denied by Janet saying, "Oh Mom, stop always having to be so psychological!"

Discussion

We constantly see the pull toward group formation and of mores irrespective of parental attitude. When the adolescent is not part of the group or when one close friend seems to be more interested in another chum or when a favorite teacher criticizes, sudden depressions occur. In the normal teenager disappointments are often ignored or even welcomed, as they provide another excuse to justify separation from parents. The charge continually made is, "You don't understand" or "Things are different nowadays." What this stands for is, "I won't talk to you or reveal my secrets, as I might enjoy having my dependency needs met and might again be tempted into a child-like relationship with you."

Adult Perspective

It is these intrapsychic phenomena that I believe suggest an answer to a question that many analysts have raised. One of them has stated[2], ". . . . . I am impressed how seldom in the treatment of my adult cases I succeed in reviving their adolescent experiences in full force . . . what we fail to recover, as a rule, is the atmosphere in which the adolescent lives, his anxieties, the height of elation or the depth of despair, the quickly rising enthusiasms, the utter hopelessness, the burning—or at other times sterile—intellectual and philosophical preoccupations, the yearning for freedom, the sense of loneliness, the feeling of oppression by the parents, the impotent rages or active hates directed at the adult world, the erotic crushes —whether homosexually or heterosexually directed—the suicidal fantasies, etc. These are elusive mood swings, difficult to revive, which, unlike the affective states of infancy and early childhood, seem disinclined to re-emerge and be relived in connection with the person of the analyst."

Adults have reported their adolescence: "drifting," "vague," "eerie," "unattached," "alone and apart," "looking for somebody or something to belong to," "unreal," "nobody understood what I thought, felt or did," "isolated."

The adolescents I have seen who have not been able to tolerate real separation from their primary love objects—in other words those adolescents who have not gone through a "revolting" period—maintain the symptomatology of early and middle childhood. It is therefore my contention that the adults who do not recall their adolescence with sharp definity fail to do so because the recollections are highly charged with violent disruptive and destructive affects.

The period of adolescence is a period of destruction of primary object ties and a vigorous drive toward replacement by attachment to new objects. The symptoms seen at this time of life—whether a mild mood change, the more intense depressions (including suicides), psychotic withdrawals or antisocial activity—can best be understood as a manifestation of problems surrounding the separation and destruction of internal primary objects and finding suitable new ones. Treatment is aimed at fostering the break with the infantile attachment to parents and aiding in the substitution of satisfactory, stable and worthwhile object ties.

Minnesota Medicine Cover Photographs

In order to encourage more physicians to submit color slides for use on the cover of MINNESOTA MEDICINE the competition is being discontinued. The picture editor now invites all physician-photographers to send 35 mm. color slides of suitable subjects for consideration as cover pictures. The format must be horizontal because of printing limitations. Pictures high-lighting Minnesota seasons, places, and activities will have an automatic advantage. No limit as to the number of slides sent will be set, but all slides should be individually identified. All slides will be returned. Physicians whose pictures are used as covers will be recognized in MINNESOTA MEDICINE. We can use many more pictures than we have received in the past.

We Waited in that Office

After waiting hours in a crowded doctor's office, one patient stood up to go. He said, "Well, I guess I'll just go home and die a natural death."

What passes for woman's intuition is often nothing more than man's transparency.—George Jean Nathan

What's New?

Morton Salt Company ("it never rains but, etc.") announces a salt substitute called Half/Salt Mixture. Half/Salt consists primarily of equal parts of sodium chloride and potassium chloride and may be applicable to patients on a restricted sodium intake. The mixture also contains calcium polysilicate, dextrose and 0.01% potassium iodide. The manufacturer claims this mixture overcomes the traditionally bitter and unpalatable sodium substitute taste. This preparation is packaged in a disposable 3½ ounce table salter, now being test marketed.

A new otoscope examining system, for use in the office, has been announced by **Smith Kline & French Laboratories.** The Hotchkiss otoscope will be marketed by the SK&F representatives throughout Canada and the world. The otoscope, designed for one hand operation, eliminates the parallax error, provides greater illumination and is adaptable to photographic recording.

Hong Kong Flu Vaccine "Crash Program" at Parke-Davis Requires 64,000 Fertile Eggs Per Day

Parke, Davis & Company is operating a "crash program" to produce large quantities of vaccine to help protect the American people from an epidemic of Hong Kong influenza which medical authorities expect this winter. "We have to produce the vaccine under scientifically-controlled production and testing methods—all of which take time—but we are confident we can have a safe, potent vaccine ready by early December.

Agricultural Pioneers

Doctors were frequently agricultural pioneers. Dr. George A. Kenny determined to raise apples on his ranch seventeen miles from Salmon, Idaho. Everybody knew that the country was too high and cold for apples, everybody but Dr. Kenny who sent east for Siberian crab-apple trees. He raised wagonloads of apples and made a tangy cider which was popular at ranch parties. His apple trees are still bearing. Dr. Kenny also started a dairy, and when his cows produced a surplus of butter, he put it up in tin cans.

"Doc thinks you can preserve butter like beans," folks said.

That winter when cream production almost ceased, he opened up his tins and sold fresh butter at the trading post at Salmon.

Dr. Guillermo B. Osbourn brought roses, vines, and fruit trees from Rochester, New York, to Southern California in 1855. Soon he was shipping grapes to the East. Twenty years later Dr. John L. Dryer of Soloma made a more significant contribution to California's future as the nation's fruit bowl. He was the first to smudge a citrus grove to head off frost damage.*

Thirty-Second Annual Meeting
The New Orleans Graduate Medical Assembly

The thirty-second annual meeting of The New Orleans Graduate Medical Assembly will be held March 10, 11, 12, 13, 1969, headquarters at The Roosevelt Hotel.

Nineteen outstanding guest speakers will participate and their presentations will be of interest to both specialists and general practitioners. The program will include fifty informative discussions on many topics of current medical interest, in addition to a clinicopathologic conference, medical motion pictures, round-table luncheons, and technical exhibits. This program is acceptable for three and one-half (3½) prescribed hours and twenty-eight (28) elective hours by the American Academy of General Practice.

An interesting and enjoyable program of entertainment for visiting ladies has been planned.

A Program of Clinical Experience in Outpatient Education for Control of Diabetes Mellitus

The Diabetes Detection and Education Center, 916 East 15th Street, Minneapolis, Minnesota, has developed a program of medical and paramedical education for physicians, nurses, public health personnel, and dietitians. Classes are scheduled for the weeks of: December 2, December 16, and December 30. Rooms and meals are available at the Center at minimum cost.

For further information, contact D. D. Etzwiler, M.D., or C. B. Cohen, M.D., 916 East 15th Street, Minneapolis.

"If a free society
cannot help
the many
who are poor,
it cannot save
the few
who are rich."

John F. Kennedy, Inaugural Address

Was the duty of business ever greater? Or more urgent? Is there more you could be doing? And if you don't, who will?
The kind of world you live in depends upon the quality of the personal faith you demonstrate day by day.
Live your faith and help light the world.

Classified Advertisements

Classified advertising rates are twenty (20) cents a word; minimum monthly charge $5.00; key number, fifty (50) cents additional.

Replies to advertisements with key numbers should be mailed in care of Minnesota Medicine, 375 Jackson, St. Paul, Minn. 55101.

WANTED: GENERAL PRACTITIONERS, anesthesiologist, Urologist, Obstetrician, Orthopedist, & Pediatrician needed in growing community of 15,000. Service area 25,000. Present 83 bed general hospital. New 100+ bed automated hospital to be completed within 2 years. City has excellent industry, school system, and recreational activities. 45 minutes from Madison or Milwaukee. Future unusually promising. For more information contact: Administrator, Watertown Memorial Hospital, Watertown, Wis.

THREE MAN group in North West Wisconsin Resort, State Conservation and Retirement Area needs two more physicians adequately to serve their practice. Facilities offered are three-room physician suites, X-ray and lab under AMT technician, RN-only nursing personnel. New accredited thirty-two bed hospital and forty-six bed nursing home. Deer and duck hunting, fishing within five minutes of town. Internist most needed; generalists welcomed. Will meet any reasonable salary request. Partnership after one year. Write: MINNESOTA MEDICINE—365; 375 Jackson St., St. Paul 55101.

BENSON & ASSOCIATES: Business & Professional Collection Specialists. No charge if no collection made. Pho: 888-2242, 8601 Nicollet Ave., Bloomington, Minn.

THE WEST MEDICAL CLINIC has an opening for a General Practice Physician, on October 1, 1968. This is a five man group that conducts a practice near downtown St. Paul and also, has the Airport Medical Clinic at Wold Chamberlain Field, Twin City International Airport. Both clinics have full laboratory and X-ray services with technologists covering both fields.

The Airport Medical Clinic does industrial, occupational and Aviation medicine. FAA examinations are conducted at both clinics.

The clinic located near downtown St. Paul has a practice limited principally to internal medicine, pediatrics, as well as occupational and industrial medicine. There is only a limited practice of obstetrics and no surgery.

Salary is open and opportunity for partnership is available. Write: West Medical Clinic, 539 W. Seventh Street, St. Paul, Minnesota 55102. Phone: Area Code 612-227-9341.

MAPLE LAKE, MINNESOTA. An active established general practice avaliable in town 40 miles northwest of Minneapolis, Minn. Good school system, active community, attractive lake country. Present physician retiring because of illness. Write S. J. Raetz, M.D., Maple Lake, Minn. 55358 or Call collect 963-3920.

SURGEON; Board certified; FACS; desires part time surgical or industrial association—hours flexible. Write MINNESOTA MEDICINE 418, 375 Jackson, St. Paul 55101.

GENERAL SURGEON interested in some general practice to associate with a 2-man partnership in a rich agricultural community in southern Minnesota. Modern hospital and new clinic building. Hunting, 9-hole golf course, swimming pool. Salary open and full partnership as soon as desired. Write: MINNESOTA MEDICINE—405, 375 Jackson, St. Paul 55101.

WANTED General practitioner, to join two G.P.'s well established in north central Minnesota community 2200 pop., 65 miles from Twin Cities. Excellent office space with lab and X-ray, just opened new hospital all facilities. Assistantship or partnership. Considerable surgery and obstetrics. Hunting, fishing, golf club. Great opening for interested G.P. write MINNESOTA MEDICINE—381; 375 Jackson, St. Paul 55101.

INTERNIST AND GENERAL PRACTITIONER wanted to join a five-man clinic group in Minneapolis. Complete laboratory and X-ray with board roentgenologist. Excellent hospital staff associations. Salary arrangement to start with, early partnership. Write MINNESOTA MEDICINE—289; 375 Jackson, St. Paul, 55101.

PRACTICE FOR SALE: Well established general practice in South Minneapolis serving an excellent community, within easy reach of the finest hospitals in the State. Very reasonable, low overhead. Splendid opportunity for solo or partnership practice. Write: MINNESOTA MEDICINE—397, 375 Jackson St., St. Paul 55101.

FOR SALE: Busy general practice northern Minnesota. Ideal for 1 or 2 doctors. Clinic, 14 rooms with lab. and X-ray. Good community hospital. Fine home. Will introduce. Write: MINNESOTA MEDICINE—416, 375 Jackson, St. Paul 55101.

FOR SALE: (1) Kelley-Koeb 30 MA X-ray unit-table (tilting), fluoroscope, bucky plus all dark room equipment. (2) Portable X-ray unit with stand—for home (bedside) use. (3) 3 Unit sterilizer (gas operated)—water, instruments, dressings, etc. Phone or write Dr. A. J. Emond, Farmington, Minn. 55024. Tel. 463-8624.

SUBURBAN MINNEAPOLIS Group Practice Seeking Associates in General Practice, Internal Medicine, and Pediatrics. Write MINNESOTA MEDICINE—419, 375 Jackson, St. Paul 55101.

WANTED: General practitioner to join two young general practitioners in well-established practice in suburban St. Paul. Excellent office space with lab, x-ray, and emergency room. Salary negotiable, with an association leading to early partnership opportunity. Write MINNESOTA MEDICINE 412, 375 Jackson St., St. Paul 55101.

NINETEEN-MAN Wisconsin group located in college community of 40,000 with excellent hospital facilities is seeking additional associates in the following areas: (1) Internal Medicine, (2) Urology, (3) General Practice, and (4) Pediatrics. For further information please contact D. R. Griffith, M.D., Midelfort Clinic, Eau Claire, Wisconsin 54701.

ASSOCIATE urgently needed in busy general practice. Excellent clinic and hospital facilities. Salary open. Partnership after 1 year. Klefstad Clinic, Greenbush, Minn. Call collect: Lloyd H. Klefstad, M.D., Tele. 218—782-5275 or 4725.

TWO MAN GROUP needs a third general practitioner in a fast-growing West St. Paul area. Begin with salary and assume early partnership. Contact N. W. Howe, M.D., or E. J. McEllistrem, M.D., 1246 Gorman, West St. Paul, Minn. 55118 Telephone: 224-8001.

WANTED: G.P. to join clinic serving population area of 12,000. City has new hospital, new clinic building, two nursing homes, new Jr-Sr high school, new swimming pool, rich farming area in Red River Valley. Fishing and hunting nearby; metropolitan city close by. Salary open and partnership if interested. Write or call Warren Clinic, Warren, Minnesota 742-6231, area code 218.

GENERAL PRACTITIONER wanted to join well-established practitioner. New clinic building—90 miles east of St. Paul—city of 14,000. Early partnership with full hospital facilities. Ideal location. L. W. Picotte, M.D.; Chippewa Falls, Wisconsin.

EXPERIENCED GENERAL PRACTITIONER wants location in Twin Cities single or *small group*. Write MINNESOTA MEDICINE—368, 375 Jackson St., St. Paul 55101.

INTERNIST, Board certified or eligible, wanted to join enlarging clinic group of surgeon and four generalists. Located in growing Minneapolis-St. Paul suburb. Good hospital, schools and recreational facilities. New well equipped clinic building. Prevailing salary to early full partnership. Contact Jim E. Jenson, M.D., Stillwater Clinic, Orleans and 6th Avenue S., Stillwater, Minnesota.

GENERAL PRACTITIONERS—one or two wanted by the two local physicians and the community. Progressive, active community in Central Minn. Community has excellent schools, modern hospital-nursing home, golf course, beautiful lakes and active community organizations. For further information contact Administrator, Melrose Hospital, Melrose Minnesota, 56352. Tel. (612) 256-4231.

EXPANDING EIGHT-MAN CLINIC IN NORTHWESTERN WISCONSIN has immediate openings in General Practice, Internal Medicine and Urology. New clinic building; three accredited hospitals; large branch of the University of Wisconsin; population 33,000. Liberal first year salary, early partnership. Contact Milton Finn, M.D., 3600 Tower Avenue, Superior, Wisconsin 54880. Tel.: 715-392-8111.

GENERAL PRACTICE AVAILABLE. Retiring because of age. Fine clientele. Progressive town of 50,000 with large referral area. Excellent Hospital and University facilities. Air conditioned offices in good location. Contact T. Q. Benson, M.D., 1524 Walnut Street, Grand Forks, N. D.

WANTED: General Practitioner for staff physician on General Medical Service. Regular hours. Starting salary $14,409 to $19,771. Generous fringe benefits, including outstanding retirement program. Nondiscrimination in employment. For further information contact Chief of Staff, Veterans Administration Hospital, Des Moines, Iowa 50399.

WANTED: Young physician for association leading to partnership with four well established General Practitioners in fast growing suburb of St. Paul. Excellent clinic facilities in nearly new, partnership owned, well equipped, medical center building. Contact: A. Eugene Muller, M.D., North St. Paul Medical Center, 2579 East 7th Avenue, North St. Paul, Minnesota 55109.

GENERALISTS needed to join four other family practitioners in Clinic Group. Suburb of Minneapolis-St. Paul. Good hospital, schools, and recreational facilities. New clinic building with laboratory and x-ray facilities. Prevailing salary to early full partnership. Contact Jim Jenson, M.D., Stillwater Clinic, Orleans and 6th Ave. S., Stillwater, Minnesota.

GENERAL PRACTITIONER wanted. Exceptional opopportunity for one or two. Present Doctor leaving for V.A. Hospital. 5000 active files, 50 bed nursing home. Hospital 15 minutes, College 30 minutes. Clinic and equipment available. Contact Dr. Wm. Alcorn or John Franta, Wabasso, Minn.

ST. PAUL: Spacious suite in new split-level building, partitioned for medical offices. Other level occupied by dentist. Excellent location adjacent to large shopping center. 1504 White Bear Avenue, 774-7144.

G.P. AND INTERNIST for five-man clinic. New building, good hospital, city of 14,000 in heart of lake district. Good schools, junior college. Write: MINNESOTA MEDICINE—420, 375 Jackson St., St. Paul.

GENERAL PRACTITIONER wanted to join 3 physicians in Glencoe, Minnesota, town of 4,000, 52 miles west of Minneapolis. $1,300-1,500 a month to start, rotating night- and week-end call system. 60 bed hospital adjacent to 7 year old Clinic Building. If interested, call collect 864-3116.

He has been a doctor a year now and has had two patients—no, three, I think—yes, it was three; I attended their funerals.—Mark Twain

Minnesota Medicine at a Glance

Cutaneous Clues to Visceral Cancer—*Perry et al.* Page 1719

This paper emphasizes the association with neoplasia of several cutaneous diseases and syndromes. In the disorders presented, the skin findings should alert the physician to the possibility of an associated internal cancer.

Cryptococcosis Presenting as an Osteolytic Rib Lesion—*Kuaity and Lewis* Page 1727

A 46-year-old negro woman, diagnosed as having sarcoidosis 10 years previously, entered the hospital because of evidence of rib destruction on x-ray. Sputum cultures and cultures from the excised rib grew out cryptococcosis neoformans. Treatment with Amphotericin B led to x-ray improvement.

Multiple Endocrine Adenomatosis—*Delaney and Jacobson* Page 1731

A 59-year-old white female with a history of recurrent ulcer required gastric surgery on two occasions. A pancreatic islet cell tumor was found at the last surgical procedure.

Recurrent ulcer prompted investigation of calcium metabolism.

In June 1966, parathyroids were explored and diffuse hyperplasia noted.

The case falls into a category of multiple endocrine adenomatosis.

The author discusses this fascinating syndrome.

Blood Gas Monitoring—*Dines et al.* Page 1735

The purpose of this paper is to review problems in the interpretation and significance of the data obtained during monitoring of patients in respiratory failure. A brief review of the physiology of respiratory acidosis is presented, followed by a discussion of the derangements in man. Seven clinical illustrations are presented to demonstrate some of the problems in the blood gas monitoring of the patient in respiratory failure.

Oliver Wendell Holmes

To The Young Practitioner

You cannot and need not expect to disturb the public in the possession of its medical superstitions. A man's ignorance is as much his private property, and as precious in his own eyes, as his family Bible. You have only to open your own Bible at the ninth chapter of St. John's Gospel,* and you will find that the logic of a restored patient was very simple then, as it is now, and very hard to deal with. . . . Lord Bacon, Robert Boyle, Bishop Berkeley, all put their faith in panaceas which we would laugh to scorn. They had seen people get well after using them. Are we any wiser than those great men?

*This was an occasion in which Jesus anointed the eyes of a blind man. "He went his way therefore, and washed and came seeing."

Blue Shield wants to know you by number, as well as your name!

Payments on claims are now processed by doctor's code number, rather than name.

A missing or incorrect code number will cause confusion and delay . . . In certain cases, the payment may even be sent to the wrong person.

BLUE SHIELD
OF MINNESOTA

Whenever anxiety induces or intensifies clinical symptoms

Library
College of Physicians
19 S. 22nd St.
Philadelphia, Pa. 19103

Librium
(chlordiazepoxide HCl)

Quickly relieves anxiety~Helps improve response in psychophysiologic disorders~Seldom impairs mental acuity or physical coordination, on proper dosage~Has wide margin of safety

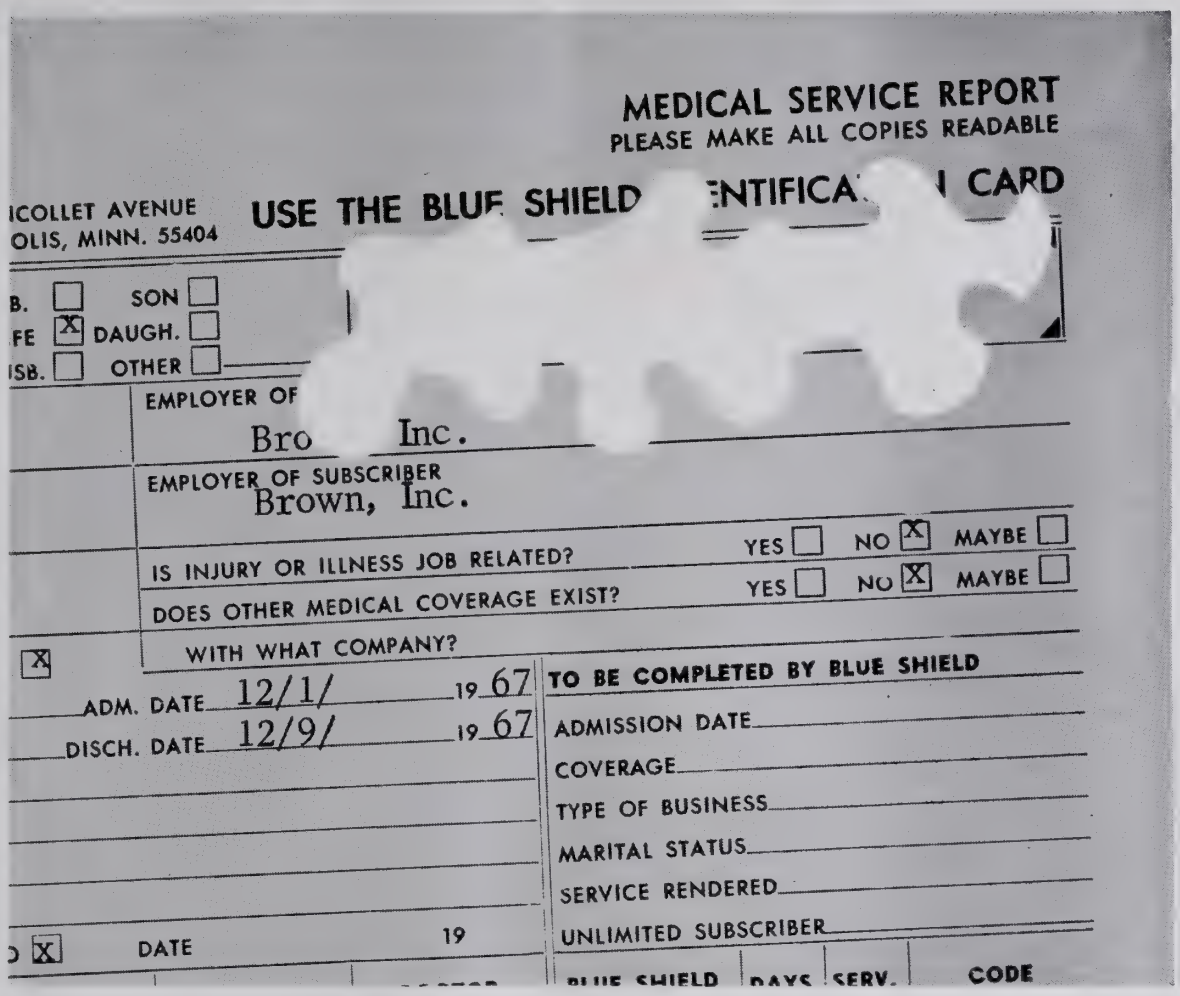
Before prescribing, please consult complete product information, a summary of which follows:

Indications: Indicated when anxiety, tension and apprehension are significant components of the clinical profile.

Contraindications: Patients with known hypersensitivity to the drug.

Warnings: Caution patients about possible combined effects with alcohol and other CNS depressants. As with all CNS-acting drugs, caution patients against hazardous occupations requiring complete mental alertness (*e.g.*, operating machinery, driving). Though physical and psychological dependence have rarely been reported on recommended doses, use caution in administering to addiction-prone individuals or those who might increase dosage; withdrawal symptoms (including convulsions), following discontinuation of the drug and similar to those seen with barbiturates, have been reported. Use of any drug in pregnancy, lactation, or in women of childbearing age requires that its potential benefits be weighed against its possible hazards.

Precautions: In the elderly and debilitated, and in children over six, limit to smallest effective dosage (initially 10 mg or less per day) to preclude ataxia or oversedation, increasing gradually as needed and tolerated. Not recommended in children under six. Though generally not recommended, if combination therapy with other psychotropics seems indicated, carefully consider individual pharmacologic effects, particularly in use of potentiating drugs such as MAO inhibitors and phenothiazines. Observe usual precautions in presence of impaired renal or hepatic function. Paradoxical reactions (*e.g.*, excitement, stimulation and acute rage) have been reported in psychiatric patients and hyperactive aggressive children. Employ usual precautions in treatment of anxiety states with evidence of impending depression; suicidal tendencies may be present and protective measures necessary. Variable effects on blood coagulation have been reported very rarely in patients receiving the drug and oral anticoagulants; causal relationship has not been established clinically.



Adverse Reactions: Drowsiness, ataxia and confusion may occur, especially in the elderly and debilitated. These are reversible in most instances by proper dosage adjustment, but are also occasionally observed at the lower dosage ranges. In a few instances syncope has been reported. Also encountered are isolated instances of skin eruptions, edema, minor menstrual irregularities, nausea and constipation, extrapyramidal symptoms, increased and decreased libido—all infrequent and generally controlled with dosage reduction; changes in EEG patterns (low-voltage fast activity) may appear during and after treatment; blood dyscrasias (including agranulocytosis), jaundice and hepatic dysfunction have been reported occasionally, making periodic blood counts and liver function tests advisable during protracted therapy.

Usual Daily Dosage: Individualize for maximum beneficial effects. *Oral*—Adults: Mild and moderate anxiety and tension, 5 or 10 mg t.i.d. or q.i.d.; severe states, 20 or 25 mg t.i.d. or q.i.d. Geriatric patients: 5 mg b.i.d. to q.i.d. (See Precautions.)

Supplied: Librium® (chlordiazepoxide HCl) Capsules, 5 mg, 10 mg and 25 mg—bottles of 50. Libritabs™ (chlordiazepoxide) Tablets, 5 mg, 10 mg and 25 mg—bottles of 100. With respect to clinical activity, capsules and tablets are indistinguishable.

ready for bed...

but not for sleep

...because psychic tension may not stop at night

The calming action of Valium (diazepam) helps counteract psychic tension and reduce overreaction to stresses during the day. Often the t.i.d. dosage schedule is enough to prevent build-up of tenseness that may interfere with sleep at night.

However, when psychic tension does contribute to sleeplessness, Valium can be especially useful. A tablet at bedtime, added to the daytime t.i.d. dosage, can help your patient be ready for bed *and* for sleep.

Before prescribing, please consult complete product information, a summary of which follows:

Indications: Tension and anxiety states; somatic complaints which are concomitants of emotional factors; psychoneurotic states manifested by tension, anxiety, apprehension, fatigue, depressive symptoms or agitation; acute agitation, tremor, delirium tremens and hallucinosis due to acute alcohol withdrawal; adjunctively in skeletal muscle spasm due to reflex spasm to local pathology, spasticity caused by upper motor neuron disorders, athetosis, stiff-man syndrome, convulsive disorders (not for sole therapy).

Contraindicated: Known hypersensitivity to the drug. Children under 6 months of age. Acute narrow angle glaucoma.

Warnings: Not of value in psychotic patients. Caution against hazardous occupations requiring complete mental alertness. When used adjunctively in convulsive disorders, possibility of increase in frequency and/or severity of grand mal seizures may require increased dosage of standard anticonvulsant medication; abrupt withdrawal may be associated with temporary increase in frequency and/or severity of seizures. Advise against simultaneous ingestion of alcohol and other CNS depressants. Withdrawal symptoms have occurred following abrupt discontinuance. Keep addiction-prone individuals under careful surveillance because of their predisposition to habituation and dependence. In pregnancy, lactation or women of childbearing age, weigh potential benefit against possible hazard.

Precautions: If combined with other psychotropics or anticonvulsants, consider carefully pharmacology of agents employed. Usual precautions indicated in patients severely depressed, or with latent depression, or with suicidal tendencies. Observe usual precautions in impaired renal or hepatic function. Limit dosage to smallest effective amount in elderly and debilitated to preclude ataxia or oversedation.

Side Effects: Drowsiness, confusion, diplopia, hypotension, changes in libido, nausea, fatigue, depression, dysarthria, jaundice, skin rash, ataxia, constipation, headache, incontinence, changes in salivation, slurred speech, tremor, vertigo, urinary retention, blurred vision. Paradoxical reactions such as acute hyperexcited states, anxiety, hallucinations, increased muscle spasticity, insomnia, rage, sleep disturbances, stimulation, have been reported; should these occur, discontinue drug. Isolated reports of neutropenia, jaundice; periodic blood counts and liver function tests advisable during long-term therapy.
